Come to think of it, I also have a nice collection of Ge diodes and transistors (all by G.E. also) from this same source. I'll have a list available within a few weeks, and I'll make them available as well.

Send for the list:

When 2Meter FM got started, it was based a lot on surplus
commercial 2-way radios that had been obsoleted when the
channels had been narrowed.

This is still a valid way to go to get a cheap 2meter rig.
Not only are there the same rigs that were around 25 years ago,
but there must be more recent surplus.

A lot of those early surplus rigs were tube-based, with solid
state equipment carrying a higher price. So there were plenty
of construction articles on building 2Meter fm gear. The majority
were for transmitters, but there were receivers too.

When synthesizers started to become practical, they too were
described in the amateur magazines.

There hasn't been much, if anything, published on building
2meter rigs in a long time. I guess once commercialy built
ham gear with all the desired bells and whistles were
available, building the gear was no longer one of the few ways
of getting it, so people stopped doing it. Or maybe because
nobody is publishing articles about building 2meter rigs,
nobody knows where to start.

If you really want to build, look in old issues of the ham
magazines. QST, Ham Radio, 73, from around 1970 to 1980 or
so. The articles are too numerous to mention. Find somebody
locally, maybe a club, that has back issues and start looking.
The rigs may not be fancy, but they dealt with the signal chain
rather than features, so they could hardly be simpler.

Of course, the surplus and the homebrew rigs were crystal
controlled. A disadvantage when you want to hit all the locally
used channels, but an advantage in terms of simplicity and
compactness. Once you've got a working rig, then you can
go back and look up all the homebrew synthesizer articles

and build one of those.

The problem with all this is your desire for a light weight rig. YOu are not going to find that in surplus. Neither will you find the compactness of today's rigs. I was at a hamfest last year and saw a handie talkie that was advertised all over the place around 1973, and I was amazed at how big it was. I'd never seen one in the flesh over all those years.

As for homebrew, again you aren't likely to get something small and lightweight. You have better control over these matters if building, but it takes a lot more effort to get it that way than just to build a rig.

One source for such filters might be a cellular phone. I had wondered about the IF frequency of them, and had been looking for a cheap used one to take apart. Last month, I came across one at a church garage sale for fifty cents. To think I was prepared to spend five or ten dollars on the exploration; the battery alone was worth way more.

As soon as I got home, I opened it up. Inside was a module with "IF" in the model number, and a listing of "freq: 83.16/0.455 MHz". Opening it up confirmed that it was the IF strip, and showed two three-pin filters, two 455 KHz filters, and a crystal marked 82.705.

This is a bit higher than I was hoping for, and I do wonder about interference from tv, but it does have possilities. It has the advantage that the crystal is right there for a second IF of 455KHz. Maybe a way of using up old Collins mechanical filter.

I assume this module is a complete FM IF strip with an input of 83.15. There's is an IC that is unmarked that I figure is the mixer/amplifier/limiter/detector.

I haven't quite decided what to do with it, but am certainly glad to get it, especially at that price.

One thing. This was the clunky old kind of cell-phone, which would explain the price. It would probably be much more difficult to extract parts from a more compact model.

Other cell-phones might turn up different IF's; I don't know enough about them to know if they are standardized.

But it is worth looking into.

It would if the people you listen to are representative of all
builders. But if the only places you hang out are where CW QRPers
hang out, then your POV is skewed. Try the TAPR SIGs, or try getting
on SSB and see how many stations with homebrew linears you work.

Poor Jeffery, too hard for you to comprehend those 1s and 0s
I suppose. The fellow who designed and programmed that VFO was
homebrewing. Those who order the kit are kit builders, of course.
The act of installing a chip in a socket, or soldering a wire
to a tiepoint is home assembly. And that's what most of your
QRP CW friends do too. It's probably what you do too, since I
expect you copy your designs from somewhere rather than *really*
doing them from scratch. Mr. Colpitts or Mr. Pierce did it first,
you're just copying (or am I mistaken, is there really a Herman
oscillator circuit now?). And (gasp) you actually use factory built

parts too, instead of mining your own ores and chipping your own galena. Shame on you.

In my view, homebrew is any home contruction requiring more skill than assembling a Heathkit. Now *that* I consider just home assembly because the instructions were so detailed that someone with zero electronics knowledge could build one, and because Heath had that "we won't let you fail" guarantee. All but the most primitive builders use factory made parts. Whether those parts are tubes or ICs doesn't really matter (other than that ICs will allow you to do much more complex things than you can with discretes). And as Ramsey proves, just because it is a kit doesn't mean it isn't homebrew. By the time you debug and modify one of his kits so that it works right, you've done more than most builders who copy their circuits from the Handbook or a magazine article.

For the most part, I consider modern kit suppliers to just be acting as my purchasing agent, hunting down and gathering the parts in one package so I don't have to do it. It is convienent, but it is no different in principle than if I hunted the parts down myself for a published circuit.

Now even when I'm building something semi-original, I'm going to search out the most efficient way to build it. If that means I use a chip, I use a chip. That involves more than "snapping" an IC into a socket (which sounds like a good way to break a pin to me). You've got to install and wire the socket too, properly decoupling it in the process (no different than if you were "snapping" a tube into a socket). And you better understand what the chip wants in the way of inputs and what it supplies in the way of outputs. And you'd better understand the chip's transfer function too (again in no way different than if you were "snapping" a tube into a socket, except the transfer function is probably a lot more complex for the chip).

There aren't many really novel circuits. Most everything is an embodiment of the same basic set of building block circuit topologies. I'm not out to re-invent the wheel when I build. I'll happily rip off any circuit idea I come across that'll do something I want done in my project. It doesn't matter to me if that circuit idea is embodied in a 5 gallon bucket full of discretes or in a single chip (other factors equal, I'll choose the chip because it likely is more compact and uses less power than an equivalent discrete circuit). I'm just trying to get some functionality I can't get from commercially produced equipment, either because they don't build what I want, or because what they build costs more than I'm willing to pay.

Getting back to that DDS VFO, try duplicating its functionality using only discretes. If you can do it at all, it'd take a six

foot rack of parts to achieve a digital readout unit with frequency memories, I Hz tuning resolution, crystal stability, and the ability to hop frequency sequences in realtime for direct FSK RTTY or even SS FH use. (One of the advantages of DDS is that one frequency change is as quick as any other because there's no more settling penalty for a large excursion than a small one. You can't do that with an analog VFO at all.)

Try Temex Electronics, Inc
3030 W. Beer Valley Rd. Phoenix, AZ
85027
(602) 780-1995, Fax (602) 780-2431

They have standard 2 or 4 pole monolithic crystal filters at 10.7,
21.4 45.0, 70.0, and 90.0 MHz and are shipped from stock on hand,
i.e. they don't have to make a production run.

They also sell crystal filter kits.
VISA and Master Card Accepted and deal in small quantities.
I've dealt with them before and have been very satisfied.
(although I still haven't hooked up the filters yet.)

I think Radio Shack and ICOM sell discones and the price is so
reasonable that it might make you wonder if you should spend time
building one. One of the two antennas is less expensive because the
center vertical element is not used. This limits the low frequency
response of the antenna. The 1/4-20 mounting screw is there, so you
could attach your own center element which would bring back the
low end. It should be noted that while discones are very broad
band, their performance is not nearly so spectacular.

Good day,

I picked up a Heathkit HG-10 External VFO the other day. Would someone have a schematic they could fax me? I want to convert it to solid state, the osc. coils are very rugged since they have ceramic fired over them. I would be happy to supply notes for the mod once it was finished. I plan to make a QRP output for each band and have it all installed in the one box, since there is plenty of real estate.

The article on the 220 transverter for use with a 49MHz walkie talkie
was in QST, maybe around 1988? I can picture the cover, predominantly
yellow and maybe with the shuttle on the cover, and there was part of
a 2part article by Wes Hayward on a 14MHz ssb transciever.

If you try this, you want to be sure to use a walkie talkie that
uses a superhet receiver, ie one of the more expensive kind. Those
with superregenerative receivers will be too wide, among other things.

The proper way to use the walkie talkie, though, would be to use a receive
converter to bring 2Meters down to 49MHz, but then change the crystal in
the transmitter to 1/3 the desired 2Meter frequency, and then use a tripler.
This is a method used quite frequently in the old days, although usually
it was to go from 144 to 432MHz.

The walkie talkie idea does make a good start, but sometimes we end up
modifying things to such an extent that it would have been simpler to
start from scratch. Witness all those articles in years past on modifying
portable am radios so they work as ham receivers; there is so much outboard
stuff that what was used in the portable could easily built from scratch.

The walkie talkies make a good source of 10.7MHz/455KHz fm if strips.
They include the maybe hard to get if filters and second conversion crystal.
They are probably no less capable than what shows up in a lot of scanners.

It might, however, be a better choice to modify the front end or skip the
built in front end and feed in a 10.&MHz signal from an external front end.
Cut down on needless conversions which exist only because you don't want
to modify the walkie talkie.

On the transmit side, is there a real reason for using the built in
transmitter with a heterodyne converter or tripler? Transmitters are
simple, and it might be much easier to start from scratch. After all,
the VHF tripler and power amplifier still have to be built, and they

might be the most expensive and difficult stages. That transverter article had to include circuitry to detect the low output power to switch to transmit; if you went to a separate transmitter you could eliminate that stage, and overall the parts count might be about the same.

I used to have an HG-10 but no more docs. As I recall, that VFO only
oscillated on 80M and that the band selection was simply rotating a
different dial scale calibrated to the harmonics of the fundamental
osc. The external radio would do the multiplication. My memory may
be foggy on this, but it might make your QRP project more interesting
with the need for multiplicaiton and filtering for each band.

> well suited.

My idea would be a small oscillator+filter powered by a 9V cell. The antenna would be coiled up inside the last stage (to be pulled out by the next-to-last stage <sp?>). Xtal control would require under five transistors (I would have to dig out the schematics, but there was an article by HaJo Brandt in the G-QRP Circuit Handbook). The whole transmitter could be covered in epoxy with space for the battery:

```
-----------------
XXXBBBBBBXXXAA
XXXBBBBBBXXXA
XXXTTTTTTXXXA
XXXXXXXXXXXXA
-----------------
T = transmitter
X = epoxy
B = battery
- = tube exterior
A = antenna wire
```

I would add padding on both sides of the transmitter.

If you need the schematics of the transmitter, I can email it to you.

Hope that helps,
Jens, DB9LL

I don't have a schematic, never had one of these. However, the Heath
ham equipment went through some line changes over the years, ie before
there was a monitor scope that matched the SB-101 line, there was a monitor
scope that did the same thing but matched earlier equipment.

Before this VFO, there was the FV-1 Vfo to go with the earlier line of
AM/CW transmitters. I would assume that the circuit is pretty much the
same. The important point to this is that in late 1972, maybe November,
after the US novice class was allowed the right to use VFO's, there was
an article on solid-stating the VF-1 vfo, and it did include the
schmeatic either original or as modified. If you can get a hold of that
article, not only would you have some information about the same basic
circuit probably, but you'd also have some idea of how somebody else
accomplished the same thing.

Kenny,

Building a 2M rig from scratch would be quite an undertaking. By your statement, "one which weighs under 1 pound" I assume you would hope to have an HT-style rig? This wouls prove very difficult. The marvel of modern electronics, particularly surface mount technology, is what allows those HT thingees (technical term) to be so darned tiny. If you're interested in building a radio from a kit, I would recommend the new Ten-Tec 2M rig. At $199, it may be a little pricey to you, but it is an excellent value. It is in a mobile-style case, so forget about wearing it on your belt.

I don't know if they have a 'net presence, but you cal call them at 800-833-7373 for more info.

Building a 2m FM would be major, an alternative may be an inexpensive
49 MHz talkie that has separate transmit and receive crystals, and
builing a transverter to mix the frequency to 14*.**. I remember
seeing something simular in some magazine several years ago for 220.

The HW-8 Handbook was compiled and published by Mike Bryce. Mike is an avid and active QRPer. The book covers both the HW7 and HW8. It has been through two editions. I believe you can still buy it from Mike. Mike is the QRP editor of 73 Magazine and the Publicity Chairman of the QRP Amateur Radio Club International (QRP-ARCI). I'm sorry I don't have Mike's address handy, but you can write to him at the address given in his 73 Magazine column.

You can buy direct from Amidon. They advertise in QST on a periodic basis.

Also, Dan's Small Parts and Kits is an excellent source of parts for projects. I don't have his address handy, but he mails out a catalog and is on the web at http://www.fix.net/dans.html. He is very popular with the QRP community. I havbe used him for several years now and can say he's OK.

Ihave an early 60's era Raytheon RAY-45, tube type, 12 channel crystal controlled marine band transceiver that I would like to use on 2-meter. I bought a set of crystals from Jan's for 146.505, however the unit will not transmit there and receive is marginal at best: ie. too far out of band. Does anyone know of a way to make this work? Changing/altering a few components is not beyond me, but is it practical?

Thank you for any suggestions,

The more the FCC allows us to "self-regulate", and the easier exams get, the less value any license has. Good point Butch, it's also affected the "higer" classes (that are actually lower skill now than they have ever been).

>into a pile of old ham mags.

Let me offer an alternative way to track down this sort of pesky problem. Use a current probe. HP sells one that looks like a logic probe, but it is really a current probe sensing the current in the trace you are following.

To use it to find a short in the +5 buss, just apply power through a current limiting resistor, chosen to limit current to 5 mA, to the 5 volt buss, and follow the buss along until the probe stops showing a current flow. You've just passed the short. It's a really easy, and really fast way to find these pesky shorts, especially on multi-layer boards.

Note, the rest of the circuitry won't be drawing current because the short is hammering the buss, and limiting current to 5 mA will prevent damage. Works like a charm.

Gary

1532. Programming Western Radio WR2400 UHF Mobile??

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-28 00:00:00 UTC
From: Jerry Sturge <jerrys@vcn.bc.ca>
Message-ID: <324CF2B8.3F45@vcn.bc.ca>
Source record: 102114

I have a WR2400 UHF mobile. It looks like it is diode matrix
programmable. But the maxtrix is empty and it just has one
diode and a little prom chip. I assume that it can still
be programmed via diodes. If you have any ideas please
drop me a line.

Thanks in Advance.

1533. BETA TESTERS NEEDED FOR PA QSO PARTY LOGGER

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-29 00:00:00 UTC
From: N3LAI@radix.net
Message-ID: <324e31fe.1767706@news1.radix.net>
Source record: 102115

Hi All,

I hope I don't offend any one by posting this off-topic message. If I do, I sincerely apologize.

I'm looking for people to test a logging program I created for the Pennsylvania QSO Party contest. I could not find any good logging programs for the contest that were Windows programs, so I decided to make one. Well, it's done to the point I can't elicit any errors. I need some people to "push some buttons" and see what happens.

The only thing I can offer in return for your help is a copy of the software at no charge. This will include any and all updates to the software any time I make any. I'm planning on making changes at least once each year as the new rules and/or sections come out.

System requirements are a 486 or better processor with 8 MB RAM (that's the only computer I've tested it on) and Windows 3.x, Windows95, or Windows NT. Approximately 5 megabytes of disk space is required for installation, and additional disk space for the log files.

If you're interested, please contact me by e-mail and I can e-mail you a copy (3 disks) or I can post it to the Newsgroup.

Thanks In Advance,

Chuck Spafford - centrex@radix.net

1537. [Q]: Improvement of Transmit Audio and Microphone Switch boxes... Suggestions?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-29 00:00:00 UTC
From: seeler@upei.ca
Message-ID: <324e3a9c.3467189@137.149.3.1>
Source record: 102119

Hi - I plan to make a microphone switch box that would enable me to switch between 2 mics (a Kenwood MC-60 with its original dynamic element; and a heil boom (with HC-4 Element) headset arrangement) and 3 rigs (kenwood TS690s, IC275 and an IC475).

My hope is to have a mike for DX / weak SSB signal use and a "good quality" / "broadcast" quality signal for rag-chewing......

I recognize that I will need a capacitor on the icom lines (0.47 - 1 uf) to prevent damage to the two mikes if I use the two mikes I have with the Icom rigs.

Since I am doing the switching with a data switch box I am also considering ways in which to improve the audio output - especially with the kenwood desk mike (MC-60). My voice - at least on HF is bassy using the MC-60 and needs some enhancement or bass reduction.... (sorry but physical type changes not to be considered :-))

My first question is this.....

Would the HC-5 Heil element improve audio output from the desk mike enough that I do not need to build an audio equalizer circuit - just change elements?

or....

Should I build an audio equalizer circuit even if the Heil HC-5 element is placed in the kenwood Desk mike to further "tweak" my audio output?

I have copies of the papers by heil (QST, July 1982: pg 11 - Equalize your microphone and be heard) and Doug Demaw (CQ, February 1994: pg 82 - Enhanced audio quality on transmit) and I am considering using Doug's circuit to "adjust" the audio from the two microphones.

Second.....

Is there a better mike, mike element or audio equalizer (cuircuit or otherwise) out there that I should consider? Would an electric mike element be a better choice over a Heil element (either HC-4 or -5)?

I welcome any suggestions or comments as to how to improve upon this area.

HAve a great week!

1538. Power splitter/combiners

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-29 00:00:00 UTC
From: aor <aor@gteais.com>
Message-ID: <324E9F82.2D70@gteais.com>
Source record: 102120

I am building a 2 meter amplifier using a pair of MRF-151G VHF transistors (300 watts each). The Motorola Application Note has the input and output transformers (and ferrite cores) to cover 10MHz thru 175 MHz. The input and output transformers use 25 Ohm rigid mini coax with cores. These are the 48v transistors.

How can I combine these two amplifiers using combiners/splitters which will cover 10-150MHz? I know how to do this for single band operation. My goal is to have 600 watts on 10 meters, 6 meters, and 2 meters thru this one amp. It will be mounted on the tower, so I will not have access to it once installed.

Any thoughts, suggestions, or articles would be a big help.

73, and thanks in advance.

Al, NW2M

1539. Any freeware UHF+ PCB layout stuff around?

*** Mid Atlantic VHF Conference ***

The 20th Annual Mid-Atlantic States VHF Conference sponsored by the Mt. Airy VHF Radio Club will be held on Saturday, 5 October at the Days Inn in Horsham PA. Technical presentations relating to VHF/UHF/SHF weak signal operating will begin at 9AM.

The Days Inn is located just north of exit 27 (Willow Grove exit) of the PA Turnpike, north of Philadelphia, in Horsham, PA. Rooms at the Days Inn can be reserved by calling 215-674-2500. Mention Pack Rats for a discount. The Days Inn is filling up quickly, so reserve soon. Additional lodging is available in the Horsham area: Holiday Inn Trevose (215) 364-2000, Marriott Willow Grove (215) 830-0550, Hampton Inn Willow Grove (215) 659 - 3535, Warrington Inn (215) 343-0373.

*** HAMARAMA ***

On the following day, Sunday 6 Oct. the Packrats will have their annual hamfest at the Bucks County Drive In Theater, about 5 miles north of PA Tpk. exit 27 on Rte. 611. Talk-in on 146.52 simplex and the club repeater on 224.58.

Ron, WZ1V has placed the flyer for the events, including a preliminary list of presentations, on the N.E.W.S. Group web page:
http://uhavax.hartford.edu/~newsvhf/hamarama.html

For more information on the technical conference or a possible presentation slot, contact John Sortor, KB3XG, at 610-584-2489 or at JohnKB3XG@aol.com.

** Preliminary Conference Agenda **

SPEAKERS TOPICS

KD1DU, Del Schier - Introduction to 10 GHz Equipment and Operation

WB6JJN, Jim -Amateur Satellites:Modes, Bands,& Issues @ VHF thru Microwaves

AJ3K, Jim Rautio, Sonnet Software - 3-D Planer Electromagnetic Design

WA1YHO, Gary Dallas - Using YO & AO to Optimize a 6M Antenna System

N1DPM -Introduction to VHF/UHF Weak Signal Operating

Harvey Kaylie, Mini-Circuits Laboratories

WB2SON, Richard Fiore - American Technical Ceramics

W3ZZ, Gene Zimmerman - 40 Years of Contesting

Preliminary schedule of events:

Friday, October 4, 1996
5pm to 11pm - Out of town guests arrive, check in.
The 2 meeting rooms be used as a hospitality suite. The Pack Rats will provide snacks & beverages

Saturday, October 5, 1996

9am to 12pm Morning conference session.
12pm to 1pm Lunch break
1pm to 5pm Afternoon conference session.
5pm to 7pm Hospitality suite.
7pm to 9pm Dinner/Banquet
9pm to 11pm Hospitality suite.

Sunday, October 6, 1996

6am to 10am Check out
7am to 3pm Hamarama at the Bucks County Drive In

1542. Re: Ideas for MILLI-OHMETER?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-09-29 00:00:00 UTC
From: wmkresl@townsquare.net
Message-ID: <52m3km$qn@herald.concentric.net>
Source record: 102124

The SCSI drive cable was one I made, and utilized keyed connectors. The initial two SCSI drive setup had been working OK for awhile. The drives are keyed connectors as well. Here's some more info regarding the events that led up to blowing TWO SCSI DRIVES, as I remember them.

o I was successfully using two SCSI drives.

o One day, I pulled the computer case's cover and discovered that the 5-1/4" drive terminator resistor was HOT. I pulled THAT drive and was just using the two SCSI drives (and another 3-1/2" drive). I thought that drive alone went bad, and used it like this for several months.

o I then tried the first SCSI drive VICTIM. With the POWER OFF, I pulled the second drive's SCSI cable and plugged it into the VICTIM drive, power connector plugged in as well. When I powered up, the fan was DEAD on the power supply and by that time the VICTIM smoked. The +5volt rail shorted. Unplugging VICTIM drive power and SCSI cable, and system power measured fine and working with ONE SCSI drive (and 3-1/2" drive). Voltage checks on Power Supply were OK.

o I then returned cables to my previously working SECOND SCSI drive. When I powered it up, I got the same results as the VICTIM drive, and KILLED this drive as well. OUCH! TWO DRIVE VICTIMS in FIVE MINUTES FLAT!

o System crippled to one SCSI and 3-1/2" drive. Thinking that the power supply was bad, I have since changed the system case/power supply to a tower box. Now running another 5-1/4", 3-1/2" floppies and one SCSI drive.

Thought I'd clear up any confusion regarding the possibility of a mis-connected SCSI cable. The drive's keyed connector with plastic housing eliminates the possibilty of being 'off' by a few pins (or backwards).

The VICTIM drive's PC-Boards are attached to the housing using SMALL TORX head type screws. I would estimate to be about a size T5-T8. Anybody know where I can find a small tool like this. (Tried SEARS, NAPA auto parts, some others...no luck).

Thanx,
Wm Kresl

Hi
it's not easy to fax when you do not leave your number!
The HG10B have been a great companion for many years and helped me to
my first DXCC in the mid 70's.

Output is 3.5 (80 meter) 7 (40-10 meter) and 8 (2 meter) MHz
depending on settings of the bandswitch.

You must multiply the 7 MHz signal if you want a proper output signal
on other hambands

Yes I can fax the schematics, I have the B version thou

Unfortunatly, I think this is way too much to ask for freeware and
"inexpensive" CAD software. Also, DRC implies netlist traceablility
which requires some kind of schematic capture capability.

The best freeware I know of is Protel's Easytraks which you can
get from their web site. http://www.protel.com. I notice they
are reorganizing their web stuff so you may have to wait a bit
before you can download from there. Easytracks is fine for digital
stuff, but has very little flexibility for RF in the way of
irregular polygons etc.

If you are doing this for homebrew boards, you probably don't
need gerber photoplot capability. I have heard of people doing
boards on some of the more inexpensive software like Correl Draw
or Illustrator. Even Paintbrush can be used.

>I dont want to go head first into this and blow $$$ on a package that I may
>rarely use.

I company I work for just paid several thousand dollars for
for a Windows based Schematic and PCB design system which includes
some of the features you asked for. I think thats about the
going rate right now...unfortunatly.

Does anyone have schematics and assembly procedures for a tube linear amplifier for the 10 to 60 meter bands? If so Please email me. I'm looking for a project that's easy to understand and build for an 18 year old with minimal technical knowledge.

>Here are some of the criteria listed:
>- Small; must fit in a 40mm tube easily.

This should be easy to meet. Simple rocket telemetry transmitters fit in our Estes rockets, with 19mm tube diameters. They were about 75mm long, however. That's because they used all discrete components. Today you can have a complete FM transmitter in a chip. The MC2800 will do. A simple beacon can be constructed with just 3 transistors, however, an overtone oscillator, a multiplier, and a power amplifier.

>- Impact resistant; shock sensitive parts are undesireable.
>- High G loads resistant; launch acceleration runs close to 50G

Pot the finished circuit in epoxy.

>- Light; will be airborne, so no heavy batteries and components can be used.

The battery is the major mass. How big it has to be is determined by how much signal power you need (not a lot), and how long you need the transmitter to operate (this may be hours if your first guess at a landing site is off). A 10 mW transmit power is usually plenty, and a 9 V transistor radio battery will run that for a couple of days. If you want more power for a much shorter time, 3 lithium coin cells can supply it.

>- Direction sensitive; we'll have to be able to locate it by means of a
> simple receiver.

Sorry, the DFing is up to the receiver. The transmitter will use an omni-directional antenna. There are a number of techniques which work well using an amateur HT or handheld scanning receiver. The simplest techniques depend on signal strength, so the receiver should either have an S meter, or have one added to it.

As you get closer to the rocket, the signal strength increases, as you move away, it decreases, so you play a game of "hot-cold" to find the transmitter. This is pretty crude, and you often need an attenuator when you get close to keep the signal strength reading from pinning the meter.

(You can even use a technique called "body fading" to find the direction of the signal by interposing your body between the antenna and the target. By turning in a circle, you'll get a weak broad null when your back is to the rocket.)

A step up from this is to use a beam or directional loop antenna
on the receiver. Then you can rotate it to get a bearing on the
rocket. Move to one side a fair distance, take another bearing,
and you'll have a fair fix on the transmitter location where the
two bearings cross. The beam will give a peak signal strength
reading when pointed at the rocket, and the loop will give a
sharp null when pointed broadside to the rocket. The beam is
more useful when you are far away, and the loop works better
when you get closer.

Another method is called the Time Difference Of Arrival method,
and the circuit is called a Double Ducky. This method uses two
vertical antennas (can be Rubber Duckies) mounted on a horizontal
(wooden) rod so that they are about 1/4-wave or less apart. The
two antennas are switched to the receiver alternately by a diode
switch arrangement driven by a pulse source at an audio rate. You
hear the switching tone coming out of the receiver when the signal
is present. When the antenna carrying rod is exactly perpendicular
to the direction of the rocket, the tone will null. This is quite
sharp, and it doesn't matter if the signal is strong, no S meter
is required. This makes a compact and handy search tool.

Moving up a notch in sophistication is the doppler direction
finder. This uses 4 antennas arranged in a circle. The antennas
are switched to the receiver in sequence by diode switches.
As with the Double Ducky, a tone is produced. But this tone
is processed through a filter and phase detector and fed to
a ring of LEDs via gates enabled by the switching pulses.
the result is that the LED in the direction of the rocket
lights while all the others remain extinguished. This rather
elaborate system works well in a vehicle, but can be clumsy
to use on foot.

Note, multipath can cause false readings with all these systems.
You want to take as many readings as you can and average them
to reduce the effect of multipath. A good bit of experience
will allow you to easily detect when you are receiving multipath
corrupted signals and allow you to discount the obviously wrong
bearings.

>- Attitude insensitive; It should be locateable either lying on the ground or
> hanging from a tree (or sticking in the dirt).
>- Simply reproduceable; we have a lot of rockets.
>- Antenna problems expected with metalic body-tubes. Any idea for this
> problem is highly appreciated.
>- Use of 144Mhz is required.

This can be a problem. Most of the DFing techniques mentioned
work best with a vertically polarized transmitting antenna.
On non-metallic rocket bodies, we used to just glue a wire
antenna down the side of the tube. If the tube winds up
lying flat on the ground, it's hard to DF until you get
pretty close. If it is hanging from its parachute in a

tree, it's a lot easier. And if it is sticking nose first
into the ground, it's pretty easy too.

If you're using a metallic rocket body, you've got problems.
A 19 inch spike antenna out the nose cone would work fine
as long as the rocket doesn't bury itself nose first in the
ground. Better is a spring loaded rod antenna with a mechanism
to deploy it out the *back* of the rocket after the engine
has burned out. Rockets rarely land tail first, so this usually
keeps the antenna in the clear.

>What we had in mind where these little transmitter posts used by radio amateurs
>to setup a game where people had to try to find the transmitter only by using
>a simple direction sensitive receiver.

Yeah, we call it "foxhunting". It would be a good idea to find a
book on this to learn the techniques. And it would be an even better
idea to find a radio club which holds these foxhunts and *practice*
the techniques. Your first time won't be very easy or very successful.
There are practical things you can only learn by doing, and this
is one of them.

> --

Hello Stephen!
I guess that one of the most simpliest ways is, to build a basic
stable oscillator with low-straycapacitance plug-in possibilities
for the L and C. Then you can use a freq-counter, or a CW reciever
and calculate your values. To be able to make a fair compare
between two coils or caps the R-loss has to be the same in the
two units to be compared, but that's probably no problem, since
you wish to sort out components of the same type.

The other possibility is to make a wheatstone's bridge, but it's a
little tricky to measure low L:s and C:s. Look in the ARRL:s handbook
for details.

good luck /Lars (SM4RZW)

Stephen,

I was leafing through the latest Popular Electronics at a friends, and there were articles on building capacitance and inductance modules for a Digital volt meter. I didn't read it close, but I think it was measuring the phase shift, anyway it looked fairly simple with parts available as a kit.

>
>Gary

Gary's suggestion would work fine, but if you want to do it on the cheap, try
this: Connect a 5 volt power supply through a 5-20 ohm resistor to the
shorted area. This will allow a limited current to flow through the short.
Using the DMM on the lowest millivolt range, measure the voltage drop along
the bus wire. For a current of one amp, expect about a 25 millivolt drop per
inch of wire. The exact drop depends on the wire size, of course. As you
proceed along the bus, the millivolts will continue to increase until all of a
sudden, they don't. You have found your short. I've used this technique to
find shorts inside multi-layer PCBs and it works great. Now, FIXING these
shorts is something else.... :-)

Maybe the shareware stuff from Ivex may help. Recently I downloaded the 100 pin shareware versions for evaluation. Although I enables me to hang up my computer easely, it appears to work reasonably if you try to avoid the bugs. The shareware version does not include a autorouter but makes PCB design a lot easier than creating the layout with paintbrush.

The Ivex homepage is at www.ivex.com and the unlimited pin licence appears to be +/- $500.

Yes, but local ordinances could very well put safety and vehicle
restrictions to work which only affect the equipment as installed
not the actual operation. I've never seen it at work, but some states
have scanner laws which have been upheld consistently. Same
would be at work here. Washington State, like Washington DC,
likes to find creative new ways to tax it's citizens.

1566. Help with Hi power HF amp (4-1000a) pi tank

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-01 00:00:00 UTC
From: ve9gj@nbnet.nb.ca
Message-ID: <52rfht$h54@agate.nbnet.nb.ca>
Source record: 102048

I am finishing up an amp construction that was started by someone else
a while back. I don't have the orginal design notes, plans etc.

My question is about the pi tank circut values

All values are for 40m

Hi voltage 4300v (under full load)
Plate current .46 amps
Grid current 140ma
Driving power about 110w
output to 50 ohm dummy load 1250w

The plate impendance using Bill Orr W6SAI's tables for a Q of 10
E\2I = aprox 4500 ohms, tune cap of 50pf inductance of 10.5 uh and
a load cap of 170pf.

Now for my problem (?) to get max out the load cap needs to be about
400+pf. To get any power out of this deck I needed to put 3 100pf
fixed caps in parallel with the 350pf variable cap (estimated).

What would cause this? I have seen another amp that needs alot more
load cap than the design calls for also.
What am I missing?
The amp seems to be OK with this extra cap shunted across the output
so I could just leave it alone but I am curious why this is.

Any ideas?

73 and Thanks

Glenn ve9gj@nbnet.nb.ca

Yes microwave CAD packages are too expensive! My company uses as an
low cost solution Superstar (to compliment the much bigger HP/EESOF
which we also uses) which cost "only" 1500-6000 US dollars.

I would as a very low-cost solution use the Visio drawing package.
They have someting called smartshapes and stenciles. One can have a
"toolbox" with corners and traces plus some foot-prints of
transistors. The layout is produced by drag-and-drop techniques. Once
you have the standard shapes defined you should be able to design a
circuit in no-time. It would even be great to trade foot-prints and
shapes amongst us here!!!

Using ordinary (i.e. digital) CAD programs are a real pain in the butt
for producing analogue circuits.

-simplex frequencies...

-Do you know of an article or circuit that could help me?

Well since you sending a single tone to your microphone input
you don't have to worry too much about fidelity, or lack
thereof caused by the impedance mismatch, but you don't want
to overdrive your microphone input. Go to Radio Shack
and buy their attenuating patch-cord. This will work pretty
well to prevent overdriving your microphone pre-amp. Then
you just need to adjust the volume level on your oscillator
for a good deviation level. Works great for me! I'm
using a Yaesu FT-290 with an adapter for the microphone plug
doing the same thing.

I'd use a Linear Tech LT1072, available from Digikey.

You'll also need an inductor, a 1N5817 schottkey diode, and a couple
of low ESR caps.

Whatever part you use, try to read LT1070 design manual. It has
everything you need to know about non-isolated switching regulators.

>

Glenn,

I don't have the tables here with me, but for 40 meters the capacity values, both the plate and the load capacitor, seem a bit skinny. Most pi-networks I dealt with had 1000 pf load for 80 meters, whcih would be 400 - 500 for 40 meters. The values you suggest sound to me like for 20 meters or so. Double check your values. It is possible there is a missprint in the book, these things do happen.

If you have acces to a grid dip meter, turn off the set and grid dip the final tank, make sure it resonates on 40. You might be doubling in the final tube from 40 meter exciter to 20 meter output.

And using fixed capacitors across the output is a time honored way of doing it. The designs I've seen, have a switch assembly that switches in fixed capacity steps of less than the variable, so you can get any value from (nearly) 0 pf to say 1000 pf. The Johnson Viking was one of these.

A more modern solution, brought about mainly by the Japanese tube-type transceivers, was to put in the fixed capacitor with the band switch. This arrangement does not have much range in the way of impedance matching, but is fine for 50 ohms with swr up to 2 or 3. In the old sets, with the separate switch, you could just about load any piece of wire, as long as the variable capacitor did not arc over.

In one of my setups, I took a wire somewhere in the 100 ft range and ran it out my 2d story window to a tree and plugged it into the

antenna jack in back. Could match any band, 160 thru 10 and load up. Other lengths sometimes needed pruning, which is easy if the far end of the wire is on a pulley and you just reel in a couple of feet and snip it!

Watch yourself with the 4-1000 amplifier. Lethal voltages and big, nasty r.f. arcs and burns can result. I set a tree on fire one time with the end of my antenna touched the branches and my 1 kw pair of push-pull 810's. 40 meters.

I heard that there's a longwave amateur band somewhere around 100 kHz or 200 kHz for experimenters.

Could someone tell me the exact frequency range of the band? Also, I heard that it's not really an amaeur band, but actually it's open for anyone to use, as long as a few restrictions are kept. Could someone tell me what the restrictions are? Also, is only CW allowed, or is AM and LSB/USB also permissible?

In addition, could someone tell me where I can get schematics for a homebrew transmitter for this band?

Thanks in advance.

>a load cap of 170pf.

That looks ok. It takes a capacitive reactance of just over 45 ohms to make
a Q of 10. Most people simplify the formula to Rp/Q = Xc, which would then be 45 ohms.

The Q should be a minimum of *one plus the square root of Rp/Rload* for the network to operate reliably as a pi, so you really need a Q of 10.5 or more. I'd be safe and use a Q of 12 or 14, you are below the normal edge of operation.

You need about 61 pF anode C, 9 uH and 355 pF load minimum, and I'd probably use even more capacitance and less inductance to be safe. At lower drive levels or lower load impedances, or with a load is slightly inductive, you will need even more loading C, even if you get the anode Q right. Also remember the plate tuning capacitor is shunted by the anode capacitance and choke reactance, so it may be several pF off from the calculated value.

>Now for my problem (?) to get max out the load cap needs to be about
>400+pf. To get any power out of this deck I needed to put 3 100pf
>fixed caps in parallel with the 350pf variable cap (estimated).
>
>What would cause this? I have seen another amp that needs alot more
>load cap than the design calls for also.
>What am I missing?

The Q is too low and remember the formula you used to determine the operating impedance is a VERY rough approximation. The true anode impedance is NOT E/ 2 Ip for any stage, unless you are a very lucky guy. The correct value is generally quite a bit differnt, and can only be found by doing a Chaffe analysis of the tube.

Since you are running the tube in a mode that is not documented in any of Eimac's, I could only do a Chaffe analysis by plotting the constant current curves of the tube. So Can't help you there.

My best guess is the anode impedance is a bit higher than 4500 ohms, since the approximation Orr uses is really almost a guess. All of these little errors add up, and to me it looks like you are too far on the "light" side

of capacitance.

By the way, the gain you are seeing is typical of a 4-1000A at that anode voltage in grounded grid. They are not very high gain tubes because the driving impedance is pretty high in grounded grid.

Its not an amateur band. It is a part 15 section experimenters band
which extends from 160 to 190KHz. If memory serves, power is restricted
to 1W max dc input and the antenna is limited to 15 meters in length
including the feedline. As for modulation, anything goes as long as
you are within the band confines.

As for gear, search for some of the VLF and LOWFER web pages.
Lots of stuff there.

Assuming you output impedance is very close to 50 Ohms, you may have the right components there now. I played with your tube operating conditions (instead of doing what I should be doing) and, for the desired output network phase shift of -135 degrees in the 4.5K-5K-to-50 Ohm range, the output C should be about 500 Pf and the L should be 7.5-7.8 uh. The operating Q calculated out at 14, 70 pf to tune. I imagine you have 20 pf in strays. Sounds like you're right where your wanted to be--no matter how you got there.

It is possible. It was done in the early days of CB, by changing crystals,
because the rigs even then were cheaper than similar ham transceivers.

Then there was little mention of the concept in the ham magazines, until
nearly twenty years ago when the change to 40 channels and the later bust
meant there were plenty of CB rigs cheap.

If you look in 73 magazine in the late '70s/early '80s, there were plenty
of articles about converting specific CB sets. Once the idea got going,
people started converting all different sorts, from crystal controlled to
crystal-based synthesized to PLL synthesizers. Find someone or something
(like a library or ham club) with a good collection of back issues, and
start studying.

ONe thing to watch. Later CB sets were designed so they could not
be moved easily if at all. The idea was to eliminate unlicensed operation
with out of band CB sets, but it had the side effect of making newer
CB sets directly useful to hams.

Perhaps I should have mentioned I work in the avionics industry. Who'd like to fly on an airplane with PCBs repaired that way....raise your hands.

Our policy is any PCB with an inner-layer short is scrapped, no exceptions. The technique is useful for proving that is indeed what is wrong. For personal, use at home stuff, well, maybe.

You can probably simply repeat the inner sections of the filter with good
results. I have used this technique with good success for Butterworth
and other filter types.

Good luck-
Larry

Allen-Bradley AB and Ohmite type J industrial pots are very high quality
items. They use, I think, a graphite brush for a wiping contact on
composition elements, rather than a metal brush on a deposited carbon
element.

HP and Tek gear uses these. Need I say more?

An easy one!
I use the LM78S40 for similar aplications, it should be possible to
use the chip's internal switching transistor and diode. This would
then require only the addition of a few resistors, capacitors and of
course an inductor.

Best of luck...Steve G6ALU

The subject may be a misnomer. Since buying a new (to me) house, I have pondered the eternal question of how and where to route 4 coax lines and 1 rotor control cable. I've considered (and rejected) the old "remove a pane of glass, substitute plexiglas and route connectors thru it" method because I'm working with both internal and storm window setup. The other method is either through the attic or under the floor in the crawl space (shack is on first floor) but the delimma is how to feed into shack. I've checked the only catalogs currently available to me for connector feedthru arrangements on both sides of an aluminum plate attached to either floor or ceiling but can't find what I'm looking for. Admittedly, my collection of catalogs is meager at the moment having cleaned house (at XYL's insistance prior to moving). I know a solution exists for a "clean" arrangement. Anyone have a solution or point me in the right direction? Any help would be appreciated. I've already missed almost a years worth of DX chasing and "Closet Contesting" work and my shack is still in storage for another 2 weeks or so. I'd like to get this setup complete before the furniture arrives.

Thanks for any help.

You can find a lot of plans and parts nos in any ARRL Handbook or in ARRL antenna book. I was faced of handling 1 KW and the hit is the ability to support high voltages when SWR and/or line impedance ist high. The mentionned books are remarkable for this subject.

From: kc5ng@dlep1.itg.ti.com
Message-ID: <5332e8$p2k@sf18.dseg.ti.com>
Source record: 101993

I'm curious... why do you need exactly 12.0 Volts?

What you're asking for will be mighty difficult to do properly. Regulators require an input of at least a couple of Volts higher than the desired output to maintain regulation. A car battery will not provide this unless you are charging it at the same time with a higher voltage. A fully-charged car battery will be around 14 Volts, and it discharges to less than that, so the regulator will not be able to maintain regulation.

If you're running any kind of radio gear (ham, CB, commercial, scanner, etc) that's designed for "12 V" service, it will do just fine at up to about 15 Volts. Keep in mind that the normal operating voltage of a car electrical system is about 14 Volts when the engine is running.

Mark,

The band you are referring to is the 1,750 Meter band (170 to 190 KHz).
Operators on this band call themselves LOWFERs.

You're allowed to use ANY mode of transmission, with a maximum output
power of one Watt. The TOTAL LENGTH of the antenna AND feedline may not
exceed fifty feet (most LOWFERs use a 50' wire, or have the transmitter
located at the base of a 50' vertical with no feedline). This part of
the frequencyt spectrum is VERY noisy, so some sort of low-noise receive
antenna is a must (a ferrite loop, for example).

There are no licenses required, although the FCC encourages hams to use
their callsigns as identifiers when on that band.

There have been some articles in the ham magazines in recent years about
the 1,750 Meter band. Check back issues of QST, 73, etc.

I don't have a data sheet for that part number but I do have 10 watt
900 MHz modules by Mitsubishi, Toshiba and Matsushita. These are
functionally identical, about 2 1/2" long with 5 leads. The Toshiba is
an S-AU11 which may bear some resemblance in numbering to what you have.

If these are similar to what you have, I suspect you can count on them
as being class C devices with three stages internally. Only the first
stage is likely to be biased for small signal use.

I have successfully rebiased similar amplifiers for class A-B service
but it requires some surgery. There's no guarantee that they will be
as linear as might be possible either.

I don't know of any linear power bricks for the 900 MHz band like those which
are available at 400 and 1200 MHz.

Hi Ted OM,

The easiest/best method I have found is the most direct one. Select a spot in the outside shack wall, and bore a hole through to the outside. Stay away from obvious areas of conflict
like near an AC outlet, to avoid internal wiring. Make a small pilot hole to check for obstructions before using a flat bladed wood drill to make the larger hole(s). If there is insulation in the wall, bore the drywall side large hole first, then push the insulation out
of the way, and complete the drilling of the outside hole through the sheathing and siding. The cables can be brought through one or more 1 to 1-1/2 inch holes. This is not as drastic as it sounds; these holes are easily caulked when the cables are through them, and are easily
repaired later on if you move or decide to move the cables. I also run 450 ohm ladder line directly through one of these holes, with no noticeable effect at 1KW. (There is nothing but
wood or drywall near it). For a whole lot of cables, a rectangular hole can be sawed after boring the four corners, and a nice metal plate installed with bulkhead conectors. I trimmed

around the plate with moulding to match the rest of the room. This is also easily repaired if/when you move. I did this at my last QTH.
If you have access to the crawl space underneath and can find a convenient place to get the cables into the crawl space, you can bore a hole up through the floor, close to a wall, and bring the cables up that way. If the floor is carpeted, cut the carpet with an "X" shape
with a carpet knife first, then pin the carpet out of the way while boring the hole. Later on if you change the location, the carpet can be made to lay flat again with very little noticeable effect after you plug the hole in the flooring.
It is incredible the extremes I have seen some ops go to to avoid the obvious best solution: make a hole!

73 and GL,
Don, W6JL

The Icom kit just consists of an external connector and plate to mount on
the back of the radio with attached power cable. The other end plugs into
an existing socket on the power regulator board.

> Don, W6JLHi.. I work in Broadcast Electronics.. one of the ways that we bring cables in from outside, is to have a contractor make a round hole with a concrete saw in the foundation and lay sewer pipe from the tower base to the foundation. From there it is possible to either bring the cables up through the floor, or to dress them into the wall and bring them out in a metal box. What I personally prefer is to stub up a piece of 1 1/2 inch conduit from the shack into the floor above the hole in the foundation, and bring the cables up to a junction box. They could be terminated there, and the uhf fittings put on a plate to the junction box, or they can be brought to the operating bench in a cable bundle and dressed into the equipment.. some thoughts of mine.. hope it helped.. 73 es cu en ss de k7nha

: located at the base of a 50' vertical with no feedline).

: There are no licenses required, although the FCC encourages hams to use
: their callsigns as identifiers when on that band.

Three mistakes. First, it's 160 kHz to 190 kHz. Next, it's 1 watt of INPUT power to the final stage (and the 15 meters/50 feet includes the ground line, too). And Third, you DON'T USE YOUR FULL HAM CALL. That would indicate that you are operating under Part 97 which would be illegal in this frequency range. Most of the stuff I've read or beacons I've heard use the ham calls with the letter prefix droppped.

Hello,

I found that if the capacitor was removed from across the GUNN_DIODE/GND
connection
the picture was improved 10 fold! Must have acted as a filter and reduced
the bandwidth
presented to the gunn_diode for osscillation???

I used a simple video modulated powersupply and an alarm module gunn diode
unit for the TX
side and a modified Ku band LNC and NEC1022a Sat RX for the RX side.

Full Colour/Quieting pictures where received over a very small 15m distance
with NO antenna
on either the TX or RX side, just open wave guide.

Best of luck

73

>transistor, and regulator).

You can get away with only three components if you locate the regulator fairly close to the battery, say within a foot or so. Any farther away and you should place a .1 mfd capacitor from the input to ground to prevent oscillation. It's also a good idea to put one on the output to ground, but you might sneak by without that one. Personally, I figure they're cheap, put 'em in.

My .02 .... It is gennerally a good idea to enter a structure at a single point for power, telephone and feed lines. If you cut the (larger) hole mentioned in another reply, you could mount to it an aluminum sheet (silicone caulk it) with bulkhead coax connectors feeding through. The plate should tie directly to a good ground with a large crimp connected wire. With this setup the feed lines can be disconnected at the wall if maximum lightning protection is desired. Have Fun! 73, Woody

1632. Plate voltages

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-05 00:00:00 UTC
From: gbostick@luna
Message-ID: <536gk8$o4j@news.usf.edu>
Source record: 102014
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc

In many of the HF amps for amateur radio there is a cw/ssb switch that changes the plate voltage from low on cw to high on ssb. I have read that this is to maintain efficiency at the different power inputs used. The high plate voltage makes sense, in that for a given power level a lower current would be required. To run at a lower voltage, thus requiring a higher current at a given power does not make sense. So, if you can run 1000W input with 2500V @ 400MA, what is the reason for lowering the voltage to 1700V and then having to push 588MA ? What is the criteria for selecting the lower voltage value?

This is an equal opportunity question open to all that would like to share their answers, as I am a bit weak in the hi pwr linear amp design department.

1634. CFS & CFJ Murata ceramic filters

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-05 00:00:00 UTC
From: hi80@pipex.dial.com
Message-ID: <3256e419.3197544@newnews.dial.pipex.com>
Source record: 102016
Cross-posted to: alt.radio.scanner.uk,alt.radio.scanner,rec.radio.scanner,rec.radio.shortwave,sci.electronics.repair,rec.radio.amateur.misc,rec.radio.amateur.homebrew

Does anyone know of a supplier of the full range of CFS or CFJ Murata filters, preferably in the UK? I know Cirkit sell them, but their range is limited; the narrowest one they sell is 1 khz, while I am looking for 300hz or 500hz. I would also like to find a supplier of Collins mechanical filters and Hy Q or similar crystal filters. Again, I know these are sold by manufacturers such as AOR or Kiwa, but they seem to rather more expensive than they should be, as they are sold as spares or accessories for their products.

I intend to replace some of the filters in my NRD535, so if anyone has the replacement Crystal filters for the 535 at a good price, I may be interested. I have a 1.8khz filter for the NRD that I would like to exchange for for the 300hz, 500hz or possibly the 1000hz.

Finally, I am looking for a design of a loop antenna similar to the KIWA MW loop. Unfortunately, I can't possibly afford the 350 UKP price of the KIWA, much as I would like to buy it, so building a similar design(balanced loop with DG Mosfet amplifier and bandwidth control) is the only alternative. Has anyone built a design by GF Maynard called the "WQ medium wave loop". This appeared in the UK "Shortwave magazine" in November 1986, and looks very impressive. However, the construction is VERY complex, so I would like to gather any opinions before starting on the project myself.

TIP FOR UK LOOP FANATICS:
Any experimenters with loops might like to know that ARGOS sells a product called a "TV Turntable" for around 7UKP, which is perfect for mounting a rotating loop, especially if it's completed project and a smart appearance is needed. AFAIK it is only available at ARGOS superstores. I have had difficulty in finding very wide diameter plastic pipe(12 to 24 inches) or something similar, again for loops. Any ideas?

Regards,

Joe Kirlew

I never thought of it in the way you discribe. However since we both went
to boot camp (in both ways) what would you think of sailing with guys who
passed on boot camp? Would you feel safe wondering if he would follow orders
or maybe just debate them with whoever was giving them? For me personaly,
I had a tough time with CW at first. After talking with a few people and
reading some REALLY old QSTs I figured out that the old technique of starting
of fast and jsut learning a few letters at a time was the key. I picked
up my advanced in short order. After this I tried this trick on a room full
of teenagers who wanted to learn S-O-S. I'm talking Jr High kids with
attention spans of about 1/2 second max. In a couple of 1 hour sessions they
were able to copy code groups of 12 of the letters at 16 wpm! None of them
was told that CW was hard or sucked or whatever. Anyway I didn't like
boot camp. Would I like to ship out with some "civilians"?
More important what "good" is CW? I happen to think it is relevent today.
Look at the work on VHF+ Yes, I know a lot of guys think all the work is
FM or maybe SSB. Not much voice on Moonbounce, or Meteor Scatter! A lot
of the week signal work is CW. I've made a handfull of contacts on 1296.
All CW! On HF count the number of stations on phone (and just for grins the
space they use up) than count the number of stations on CW. Surprise! While
it might not be 50-50 it is a hell of a lot closer than many people want to
admit. Now look at the space the phone boys use up. CW to me is relevent.
I also think 5wpm IS no code. Heck Uncle Wayne points out that at this speed
you might as well write down the dits and dahs. Or if you learned it wrong
like I did (at first) the Dots and Dashs. Once you learn it well enough for
it not to be a torture I think you might be pleased to meet some of the people
on the bottom of the band. They are Ladies and Gents! Can't say that about
all the phone users. Oh well. Enough said.
BTW Camp Berry Great Lakes?

Hi,

It changes the operating point of the tube, like class A, AB, B, C. In CW you typically run class C. It's a point on the characteristic curve of the tube that dictates how much plate current flows with a certain level of bias. (grid voltage) Go with the higher voltage, and tune the plate to keep within the legal limit. Most tubes drive easier with a higher plate voltage. Go to your local library or maybe some local old timer may have the Eimac 'Care and Feeding of Power Grid Tubes'. It does a great job of explaining the whole deal with load lines, impedances, and all. They're not too tough to understand. Only the Gate 2 Vanity Call operation is beyond comprehension. Cheers!

> wrt@eskimo.com

In general, you CAN'T get 12.0V out of a car battery using a linear
regulator unless you plan on leaving the motor running and use a
PNP pass transistor or very low drop-out regulator.
Also, in an automotive environment, you need to worry about protection.
Sticking an IC on the +13.6V line is likely to eventually end up a shorted device.
Use some inductance and a big cap in addition to the protection diodes
required by the regulator itself.
Thre's a lot more to this than meets the eye.

From: "J.Manuel Rivas Rodriguez" <manel@redestb.es>
Message-ID: <3257BF46.6B7E@redestb.es>
Source record: 101939

Has anybody tried to use an TWT amplifier for 12 to 18 GHz in 10368 MHz.
I supose that 12 to 18 Ghz is the bandwidth specified for the
manufacturer for full specifications. I want to use one for 10 GHz. EME
and I have the oportunity to buy one.
Any previus experience.

Thanks EA1BLA.

1644. 6M amp using 4-1000A ?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-06 00:00:00 UTC
From: scott <acepilot@mwt.net>
Message-ID: <32582BC9.1183@mwt.net>
Source record: 101941

Anybody have a good design for using a 4-1000A tube on 6 Meters? I plan to drive it with 50 Watts from my Kenwood TS-690S. With the available drive, I guess it would be better to run grounded grid? If so, would it be possible to get around 800-1000 Watts out with this amount of drive? I've seen a design (common cathode) that drives the grid with 10 Watts and 1000 out or so. I'm leery of the design as I might forget to lower my output to 10 Watts and fry my 4-1000A. Worst case, I'd like something that could take the full 50 Watts of drive and give me anything above about 700 Watts out. Any good ideas? Fax a schematic to me at 608-634-2594 or contact via email to arrange other methods of getting info to me (acepilot@mwt.net). Thanks...this will be my winter project...N0EDV.

PF0011(ceramic) and PF0031(plastic) modules 10mw in 6-10 Watt out.

Will run class AB ie OK for SSB. The unit will require 13.6 as the
supply voltage and there is a pin next to the input pin that you can use
to vary the gain of the device. It will take 0 to 8 volts to vary the
gain according to my data sheet. I am currently awaiting a module
myself for my DownEastMicrowave Transverter on 922 - 928Mhz.

Here have new IP after crash of old one. (just too much trouble to place phone call whenever I needed to post:)

I was wondering if anyone had any success with Synch AM Demod, using SD5002 in S/H ckt???

Also, believe were several requests for schematic that I didn't get to, due to fax machine problems.

If someone who received the schematic could agree to post it as an attachment as a binary file, I would greatly appreciate it, as all my schematics here are on hardcopy, and faxing pages individually is flaky at best.

That would permanently remove me and anyone else from the faxing loop. Also, realized had couple of mistakes on schematic, but competent ham should be able to get the gist of it, and get it working on any reasonable IF freq.

>it with a knife to make openings (for cables), adjustments, and such.
>
>Anyway, is this stuff bought at hardware stores, paint stores, or where?

'round here you can find it at most any home center under the name
of Great Stuff. It comes in a red can with a yellow snap off lid
(like a can of spray paint). It is already mixed and begins to
expand the instant you let it out of the can. Although, I once found it
packaged in a cardboard box with two seperate canisters inside
and a tube to dispense it from. It mixed in the tube as
you dispensed it. I have not seen it this way in the last couple years
however.

It's really aggressive stuff... sticks to absolutely everything.
I would be really, really certain that whatever equipment
you are going to foam in is safely sealed in some kind of bag or wrapper.
It will most certainly ruin the finish (or front panel!!) of
any piece of gear it contacts.

Another idea is to visit one of these mailing/shipping/packing
stores. The one's around here go by the name of Packaging
Store. They have the two part, foam-in-place stuff on tap
and will package things for shipment using it. They also
wrap the item in fairly heavy plastic or put it inside a plastic
bag before foaming. We have packaged and shipped several
pieces of test equipment over seas this way.

Good luck... but be careful with that Good (and nasty) Stuff !

1651. Wanted: Test Equip

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-06 00:00:00 UTC
From: Richard Hager <rhager@millcomm.com>
Message-ID: <32587D9E.2001@millcomm.com>
Source record: 102024

Hello,

We are a manufacturer of CNC controls for machine
tools. We'll trade brand new controls or control
components with full warranty, for test equipment.

If you've been wanting to add CNC capability to your
shop, and have some unwanted test equip sitting
around, please let us know. This might be a good
deal for schools, universities, or large corp's with
surplus test equip on hand. Individuals welcome also.

Items WANTED:

-Tek current probes, A6202 w/AM503 amp. 2-6 pieces.

-7104 mainframe, especially w/7A19-7A29-7B10-7B15 plugins

-2467, A, B Tek scope w/probes.

-Modern Digital Scope. Open to suggestions

-In-circuit emulator for 486. must be complete & working.

-Spectrum Analyzer, standalone or 7000 type plugin
Like 491, 492, 7L5, 7L12, 7L14, etc..

-Also interested in low-freq FFT type for vibration and
control system analysis. Like HP, Stanford Research, etc.

-RF Generator, like HP8640, etc. 1 or 2 units covering
10khz to 1ghz.

-Function gen w/lin-log sweep, minimum top freq. of 11mhz.
-Pulse Gen, 50mhz min, 100mhz prefered. w/variable risetime.
-Sweep Gen, 1-500mhz

-Tek curve tracer, 576. Hi-pwr fixture a plus.
577/D1 is a possible alternative.

-Tek DCS01 capture camera.

-Good universal freq/period counters, like HP5315/16, 5345, etc.

-Tek TM500 plugins for scope cal setup:
Sweep gen plugin
Time mark gen plugin
Dual trace Scope plugin
500mhz counter plugin

Leveled sine wave gen.
FGxxx function gen for TM5xx, prefer FG504.

-Tek 7000 series equip:
7A12/7A26 2-ch plugins
7A42 4-ch plugins
7B53A timebases
7B92A timebases
7T11A and 7S11 sampling plugins
7B10/7B15 timebases
7000 series cal fixtures and equip
7000 series spectrum analysers, 7Lxx

-Regular Tek scope probes, 6105, 6106, etc..

-Other equip will be considered also, for example:
Fluke 8060A DMM's or equiv. And/or good bench DMM.
Temp measurement stuff, especially IR thermometers.
Grid Dip Meter, LCR meter/bridge, Q-meter, ???

-Also looking for some older stuff for personal
restoration project: 564B, 3T77A or any 3Tx

Please send email to address below, attention Richard.
Info on CNC controls is at the web site address below.

Thanks!

Richard

1652. vacuum variable tester

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-06 00:00:00 UTC
From: three@3rdplanet.com
Message-ID: <three-0610962300190001@ppp-dialup1.3rdplanet.com>
Source record: 102025

Saw article nervously asking about vacuum variables someone bought at flea-market.

Here, I have been very lucky in finding ones (like 2000pf @ 3kv and 500pf @15kv at that non-descript "junk store" in Sacramento, Ca. in 1987. Both for $75 and now in my 8877 amp.

Those kinds of deals still exist, but you really need to be careful to buy units that do not have the seals broken.

First indication of a good vacuum variable is the sight of perfect unoxidized copper surfaces inside the device. Sometimes its hard to see the insides, due to wear, etc on the outside of the unit. I've bought some that looked as if they had dark brown copper metal on the inside, only to find that it was some film on the glass making it look that way.

On the other hand, I have bought units that looked like perfect unoxidized copper on the inside, only to find that the unit glowed purple when installed in an amp.

>>>> The only way you can be sure is to buy either from some well known company, like Peter Dahl, or make yourself a simple high voltage AC source from an old TV flyback transformer, that you can operate off 6 D batteries in series, and take to the hamfests. It might look silly, but you'll have the last laugh when you get that incredible vac variable deal.

There have been alot of articles about HV sources from TV flyback transformers, but the simplest is to wind extra 10T and 1T windings on the bottom of one, and then hook the 10T one between collector of 2N3055 and 12VDC supply, while connecting the 1T winding between GND and 1.0uf polyprop cap to base of the 2N3055. A 1.0mh choke goes between junction of 1.0uF cap with base, to ground, and the emitter of 2N3055 is grounded.

With 12v applied, you should get 10-30kv or so. In fact, may need to put resistor in series with 2N3055 base, to limit HV!!.

You figure out how to put it into simple box for carrying around at hamfests, or suprising your friends when they grab that doorknob.... just kidding, will usually resonate arount 30-40khz, which is way above human electrocution frequency potential.

Good luck to you with some Tesla technology at your disposal!!! Rob.

For the most part they do not make good ham 10 meter rigs. They
are channelized, so they do not have continuous coverage. Also,
they are mostly a.m. sets, although there are ssb ones out there.
Most of the ssb sets are not very good. The filters are broad as
there is no close by interference on CB...only the next channel
which is pretty far away. They have no provisions for CW. Their
power is low. They are "built to a price" and usually are not very
reliable.

> Aeronca Super Chief !

I've flown one of those!

Okay, with just 50 watts you do not want grounded grid, but actually drive your 4-1000 grid. This could be a very simple circuit.

On grounded grid you would need an input tuned circuit; you will not need this on grid driven with 50 watts to spare. You could do this:

Calculate if 50 watts across 50 ohms is enough voltage to drive the 4-1000. If it is, then put a 50 ohm dummy in the amplifier and hook your grid to it, via a capacitor so you don't short out the bias voltage, which has to be fed via a choke. Or, you could do it the other way, feed the bias to the grid via the 50 ohm resistor. Put a bypass capacitor from the bias supply end of the resistor to ground. The hot end (grid end), connect to the center conductor of your input coax connector with a capacitor to block DC. A good mica capacitor of 500 pf, or .001 mf will do. Check to make sure it does not get hot in operation, and check your input swr.

If your calculations indicate that you cannot develop the rf voltage at the grid, you will need to find out what resistance with 50 watts across it will work. Say it needs 200 ohms. Do all the above steps, except between the amplifier and the exciter you need a ferrite unun, or unbalanced to unbalanced rf transformer. These can be bought, or you can wind one up with a little toroid core. Instructions in the ARRL handbook and Antenna Book. Don't use a Balun. It must be Unun. Possibly the simplest is to wind several turns of wire on the toroid core, hot end to the capacitor feeding the grid, other end to ground. Tap the coax connector on the windings until you find the

magic spot of 1:1 swr. Test the swr at low power with the 4-1000 amp off.

The 4-1000A might be a bit marginal for efficiency at 50 mHz. Have you checked this? The resistive input circuit I described will give you very stable operation, but be sure your filaments are properly bypassed to ground for VHF, and so is the screen, or it will break into oscillation and commit Hara-Kiri before you can reach the big switch!

I don't think you would tune for the 588ma, but some lower number
that would give the same plate load impedance. I think most
tubes like the higher volts.which makes the amp easier to
drive with lower grid current, ssb or cw... Leave the switch
in ssb for all modes.

gbostick@luna wrote:

>What is the criteria for selecting the lower voltage value?

First Part: Back in the bad old days we were allowed to run 1 KW input as measured on meters of 1/4 second time constant. Which meant that you could run as much input as you wanted as long as the meters didn't show more than 1 KW indicated. Unless you whistle a pure note, the average power in communications work is less than the peak power. Well, it all got interpreted by a host of folks to mean that, in general, you could run 2 KW input power on SSB and still keep within the power limits. Never worked that way--but that was the logic involved.

Second Part: The result of the above was that you wanted the amplifier tuned properly for two different input powers. If you use the same anode voltage and two different currents, you have (about) a 2:1 impedance shift. So, the easy way to keep the same tuning components in service at two different power levels was simply to change the anode voltage for 1 KW to 70% of the value for 2 KW. 70% voltage gives 70% current which is half power. (Tetrode amplifiers also had to switch the screen voltage.) Hence, the CW tap on the power transformer.

Third Part: People don't usually find a 3 db difference to be critical. Most times, in fact, folks could operate at lower input (and output) power to keep within the rules requiring the minimum power necessary to communicate. (A value I've always found to be about 10 KW. That's a joke, folks!)

Fourth Part: Some amplifiers weren't amenable to operating on SSB in the CW position. Unless the bias for both anode voltages was correct, you could have significantly higher IMD when operating at the lower voltage. In fact, most some--but certainly not all--amplifiers had too much bias for proper SSB operation at the CW voltage tap. The Collins 30S-1 actually changed the bias in the CW position to above cutoff (Class B-C region) to improve the PA efficiency.

Efficiency is part of the reason, but linearity is another part. In my
AL-1200, the plate idling current is 75 ma in the SSB mode, but only 25 ma in
CW. When driven to the same output, the CW mode is more efficient, but the
SSB mode is more linear. Personally, I leave it in the SSB mode all the time
because linearity is good for CW too... it reduces the tendency to generate
key clicks.

Try your local appliance dealer. He'll have replacement elements for electric dryers, and probably other appliances that get hot. They're relatively inexpensive. Or you could buy old or broken appliances (hair dryers, popcorn poppers, irons, whatever) at the Goodwill store or garage sales.

Hi Gary,

The reason for the high/low voltage was in the early days a PA could only run 1kW dc plate INPUT on key down carrier CW (about 500-700 watts out with normal PA's) , and 1 kW maximum indicated dc plate power input at modulation crests on SSB (at least 2 kW PEP plate INPUT power on SSB, and about 1200 watts or so PEP output).

If the high voltage was increased the correct amount for SSB the following would happen:

1.) The user could tune the PA on CW, and flip the switch to SSB without breaking the law by tuning at much higher power on carrier.

2.) The highest crest the PA meters would reach on SSB would be 1 kW on SSB and CW, both legal.

3.) The tube output impedance (and hence the tank control settings) would remain the same because the ratio of RF anode voltage to RMS anode current would remain the same.

This feature was slowly phased out of most amplifiers when the FCC changed the power rules.

By the way, this is why so many people "blow up" SB-220's. The SB-220 was designed to operate at 500-600 watts CW output, while dissipating about

400-500 watts in the tubes. The same with the L4B Drake.

It is also why most of the tuners sold today have exaggerated power ratings. They were rated to match the power amplifiers years ago, when a 2 kW PA would really only run 500 or 600 watts output. Most 2 kW antenna tuners really only handle 500-600 watts of CW carrier.

Murata in the UK are in Fleet. Phone number is 01252 811666 but unless you
want to open an account with a turnover of several K you won't get
very far :-(

There are several distributors who you could try. Eurodis/HB Electronics
(01204 555000) being one in Bolton although Murata should be able to point to more local
ones (if your not in the NW !)

If you know the specific filter you are after Murata should be able to
tell you which distributors have or have had that particular item. If Murata
or a distributor have no stock you will probably be stuck with minimum order
via a distributor for a few hundred pieces.

> Collins mechanical filters and Hy Q or similar crystal filters.
> Again, I know these are sold by manufacturers such as AOR or Kiwa, but
> they seem to rather more expensive than they should be, as they are
> sold as spares or accessories for their products.

Even if you do find distributors with stock they may well be rather more
commercial that you wish and have minimun order value or qty in which case
getting the single units from AOR and the like can be your best bet.

Good luck with your projects.

Actually, found that Drake still sells 160M, 10M, and WARC crystals for R4/T4 series for $15/pc. I also understand that they do not have any crystals for ranges outside the ham bands.

Like I said a month ago, sorry to ever bring up the subject of JAN on this group. I was hoping to be the "good guy" after seeing several posts very critical of JAN, and thought I'd get lots of positive posts if I asked for others' opinions who ordered from them.

Then I could send in my order and add my "positive" two cents on this group in response to the nay-sayers.... ...and everyone would live happily-ever-after... ...and the new sunspot cycle would miraculously start next week, peaking on the CQWW weekends at an averaged number of 160... ... with geomagnetic fields quiet.... and the FCC announcing that all HF bands will be expanded by 100khz... with the code requirement being abolished and the 30byte/min ASCII copying requirement being added in response to need for ops copying the new digital modes in times of emergency per new FEMA guidelines...

Puuh! I am working on two linears for 2m and 70cm at the moment. My advice: keep Your hands off a tube PA as long as You don't have enough experience with electronics. All tube amplifiers use very high voltages (1000V to over 3500V), which is ABSOLUTELY LETHAL. Try to start with a low power transistor PA to get an idea. The Motorola RF databooks have very interesting application notes about that (most from Helge O. Granberg, K7ES).

If You definitely want to build a tube PA: the ARRL handbook has some designs. Older ones have a design using TV deflection tubes. Advantage: 'low' Plate voltage (800V), cheap (but nowadays hard to find tubes).

Try to get advice from tube specialists. I am in luck here and I can tell You, that I would have made everything smoking, if I hadn't have my plans revised by some very experienced radio amateurs.

Hope this helps

Regards

Robert HB9NBY

Are we making this a bit complex? If the load is consistant .ie a
specific application wouldn't a simple crowbar regulator
with a 12 volt zener diode work?

13.8 to 12V yes. Battery will eventually drop to 12V (or less) after
charging stops - then you need a zero drop regulator.

The only possibility is and "inverter" type circuit that would increase
the 12 volts to something higher and then regulate it back down to 12
volts again.

If you want to take the TV deflection tube approach, just consider "weird"
filament voltages. Tube types 23LQ6, 31LQ6, etc., are still readily
available at a good price (typically USD 4-10 each) from commercial
sources (such as antique electronic supply)...

I have found a useful extension of this idea if you tinker with/add
antennas. I made a 2" diameter hole and put a section of PVC pipe in
it. On the outside I use a 90 degree elbow pointed downward to keep
rain out and force a drip loop. If rodents are a problem you can stuff
something removable in to seal the hole. For coax a metal pipe works
too. And, if you ground it might help keep lighning out of the shack.

Use an LM317 or similar adjustable voltage regulator on any transformer
with a rectified no-load output less than 35 volts.

You can find the schematic for this everywhere.

There are also some higher current versions of the LM317 available
if 1.5 amps isn't enough.

When trying to determine if a vacuum variable capacitor is good, do not forget the obvious---it should have vacuum! After determining that the copper inside has not tarnished, unscrew the leadscrew that activates the internal assembly through the bellows. Insert the leadscrew in place and attempt to pull apart the plates. When pressure is released, the activator should return all the way with considerable pressure. If not the capacitor is an ordinary one, not vacuum! Cliff Buttschardt K7RR

One way to build a power supply that combines the good transient
response and low noise of a linear regulator with the high efficiency
of a switching supply is to use a switching supply to regulate the
raw power supply down to about one or two volts higher than the
desired output voltage, then use a linear regulator at the desired
output voltage.

Though I haven't tried it, it shouldn't be too hard to make the
switcher track the linear supply, so you'd only need one voltage
adjustment.

Using a PNP pass element would allow a very small differential
on the linear supply (under 1V).

This isn't that hard of a project, though it isn't a single-chip
one-evening job.

Have a look at the Texas Instruments Linear Databook for some
excellent material on designing power supplies.

You have got to be kidding me. Several people voice their opinions and
personal
experiences with a particular company and you want to notify that
company of each
and every one who has done so.

Try this hypothetical. I go to club meeting and ask about a particular
brand radio. Then I write down the calls of every HAM with a negative
opinion and when I get home I run each call through a CD ROM database and
then send a list of names and home
addresses to that manufacturer. How does that sound. I think it sounds
fascist.

I just wonder how many honest responses will come back to the newgroup if
this
practice continues. DON'T KILL THE NEWSGROUPS! BE RESPONSIBLE!

1680. Re: CB Radio to 10 meter

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-07 00:00:00 UTC

Source record: 101962

Converting CBs to 10 meters was a popular pastime back in the late 70s and early 80s. There were a number of articles on the topic in 73 magazine during that period. Check with your local library.

The most common conversions used the "crystal synthesized" rigs. In these rigs a set of 6 crystals is mixed with another set of crystals to generate the various CB channels. By changing one or both sets of crystals a series of "channels" could be created in the 10 meter band. I don't think there was ever a standard set of "channels", however I doubt this would be much of a problem if 10 was open.

73,
Bruce

1681. Re: S&S TAC-1 QRP Kit

Source record: 101963

I built the S&S TAC-1 40 meter kit and wrote up the experience for Worldradio. It was published in July 1996. I'd suggest you try to find a copy.

In general the TAC-1 is a very high quality radio. All components are full commercial spec and the quality rivals mil-spec in many respects. It is not a difficult kit to build, even if you have little or no experience, if you go slowly enough. My advice to prospective builders was to follow the carpenter;s rule: Measure twice and cut once! The most uncompromising part of this kit is the use of multi-layer boards with plated through holes. They are a joy to solder, but woe unto you if you stick the wrong part in the wrong hole. They are an absolute &%$)*@@ to unsolder.

Follow the instructions. Chack and double check the part before soldering. Go slowly. NEVER believe you have a better way than S&S to do something.

I use mine frequently. I like it very much -- it's a keeper. I even popped for the accessory keyer!

I know Dick and Kathy peronally. It would be hard to find a more dedicated pair. They are honest, willing to help, and a joy to work with.

73 and good luck,

Bruce -- W6TOY/3

Source record: 101965

I'm trying to locate a source for the MuRata 455J1 filter
used for the Epiphyte-2 SSB QRP radio. Apparently this isn't
actively marketed in the US (thats what I've heard).
I need 3 or 4 for a few friends that are also interested
in building up these cute little rigs featured in QRPp.

I've decided that perhaps life isn't too short for QRP ;^)
Any ideas? anyone else have luck finding them?
I'm not oposed to ordering from a source in Europe if
necessary, although finding them in the US would be a plus.

Thanks greatly,
Ed Burress

1686. 201-A grid leak resistors, Crosley "Pup" & other impertinences

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-07 00:00:00 UTC
From: nyoung@desire.wright.edu
Message-ID: <1996Oct7.212001@desire.wright.edu>
Source record: 101968

Ok, so now I understand how the grid leak leaks and how the resistors resist, but I still don't understand this old radio. Youze may remember that I'd picked up a home-brew one-tuber at a local antique fleas market. It had an 201-A in it... and the tube even still has a filament. But it had been rewired a couple times (I figure) and someone had stuck a 1/4" phone jack in the front panel.

So here's the deal(s): What is the composition of Ebonite? I figure that the front panel is Ebonite, but it's kinda like been bleached or something. It's now kinda brownish/tan color, but under the knobs and on the inside of the box it's black. So I figure that it's Ebonite. Seems fairly heat resistant. (I'd replace it with tempered Masonite, but for I wanna have evidence when I croak that I did not destroy a family hairloom to fix it up.)

2. I had to desolder the grid leak C&R pair from one of the capacitors and put it back on the board what the radio was built on. Only one problem: the resistor measures about 2.5 k instead of 2 M Ohms. It's one of them old-fashioned thangs with a green body, a dot of brown in the middle and a dot of black on one end. (And yes, I do have old books to see what it was s'possed to be.) SO... if the tube is a 201-A (like it says on the base), am I asking too much that the grid leak resistor be 2 Megohms? I can't figure that a garden variety triode like the 01-A or a 45 (I think it is) had such a grid cut-off point that it'd use a 2.5 kOhm as a grid leak. Any hints?

3. The panel has two variable caps and two sets of switch points for taps on the coil. I hooked the beast up with antenna straight to one set of taps (the ones closest together) and rigged the two caps like in the MRL #2 crystal set. That meant that the other set of taps (more widely spaced) let me tune the 500-1600 kHz range and hear pretty much like a crystal set (with a 1N270 diode instead of the tube...I ain't that far along yet). Seems to work. I'm now having to consider finding a vintage RFC and plate RF by-pass capacitor, among other follies, in order to at least get close to what this beast might have been. SOmeone suggested the Crosley "Pup." Anyone wanna front me a copy of a schemo for one of them puppies?

4. All suggestions to take this to rec.radio.antique.old.geezer. brainless.pioneer.wacko have been followed. That's why I'm back here: t' pester yew young pups lack yer parints shoulda

in da first place if they hadn't kept me from my tapioca. SO

Is very good point. However, levels of air contamination that cause
problems are so small that devices may carry a vacuum for years and still
not function as a capacitor- more like an OA2 tube. HeNe laser tubes
suffer from the same problems, but sometimes if you're lucky, gas is
absorbed after bias applied over a few weeks or so. Doesn't seem very DX
friendly, though, if you have to wait a few weeks to transmit for that
elusive QSL.

Hello.
I've just updated my FTV program, which does FAX & SSTV using a SoundCard, to decode Baudot using the same (FM) demodulation engine.

Here is a run down of the more interesting features:

(1) It keeps the demodulated signal in memory, so that the signal can be analysed again at a different keying rate or polarity! Garbage can be resampled on the fly, which means that minutes of received signals decoded at the wrong baud rate or keying polarity are recovered, on the fly, while still receiving.

(2) Keying rate and polarity are analysed automatically - standard baud rates are automatically set following analysis.

(3) Tuning oscilloscope available at all times, without loss of copy.

(4) Program works in real time.

(5) I wrote it, and I love it - I myself can't believe it works so well!

Download your copy of FTV from my web site, at:
http://www.geocities.com/SiliconValley/2504

System requirements, and the standard features of FTV are described in the following page:
http://www.geocities.com/SiliconValley/2504/ftv.htm

By the way, AM signals from low orbiting weather satellites are also decoded - no extra interfaces needed. Demodulation mode is user selectable in software.

Hope you all have a load of fun receiving 'words and pictures' - I hope to get some feedback !

All the best from Brian, 9H1JS, on the Island of Malta.

> 73 + Good DX + Good Contest !

Hello Pedro,
I use an HC-4 element with an IC735. A .047 or .1uf capacitor
should go in series with the microphone element to isolate it from the
8 volt DC supply voltage that is fed through the mike line. This is
the purpose of the capacitor. As long as it is large enough to pass
audio frequencies, all is well. If it is too small a value it will
attenuate low frequencies (which the HC4 already does, so this would be
too much).
Will be searching for you 26th-28th, or if we get our amplifier
working maybe you'll find us first!

Regards,
Pete

> Any previus experience.
>
> Thanks EA1BLA.
In my experience TWT's are very braod band. I use a 6GHz tube
at 2GHZ, 3GHz, and 10 Ghz. I get 8 watts, 10 watts and 10 watts
respectively, out of the 18 watt 6ghz tube. This tube has N type
connectors.

Waveguide RF connections tend to limit the band width. But the tubes
I have seen have waveguide that has a lower limit at 10GHz which menans
that they still work at 10386 Ghz. The seem to work quite well. If you
can try it out it would be best.

hello and thanks for reading,
i have a swan 250 c six meter radio. i am having a problem with the
transmit being on frequency. the radio receives fine but i can not get the
transmit to line on freq.
if anyone has had similar problems, or have any suggestions, please
e-mail a response.
any help is appreciated and all mail will be answered as promptly as
possible.

I just found that the crystal supplier that I had used
in the past now has a $50US minimum order.

So, who do _you_ order small quantity crystals from?

tnx es 73

I havge the TAC-1 and the ???? (I forget the model number but it's the
40-meter rig, the first one theyput out).

I built both of them and operate them both. (Right now I am off the air
because I am in themidst of moving from Northern Virginia to east
Tennessee.)

Anyway, I highly recommend the S&S Engineering kits.

- They use only top quality parts.
- The designs are excellent.
- ON the air performance is top notch. In half my contacts I am asked
about the rig and get compliments on the keying.
- Building the kits is not simple but not difficult. Be careful. Read
the directions, look at what you are doing, double check, work slowly.
These are full-featured radios and the circuit boards are packed.

Go for it. You will not regret it.

I believe that England now has an authorized ham band down at 80 or
100khz, with some power restriction and only CW. Seems like I read this
in QST recently. There is a move to get the FCC to give US hams an
assignment on VLF. It would be interesting if we could run enough power
to overcome the necessarily inefficient antennas most would have to live
with. Still, there is a kinda magic about VLF.

Lioenl N5LB

PS I've never heard anything on the LOWFER band with my TS850 other than
light dimmers and who knows what.

Gudday fellow HomeBrewers..

Just revived my Old Lowfer Transmitter and it is on 186.700 khz. +/- .5 hz..

I am 20 miles south of Boston on Coast with the ID on CW being '1A'
Soon will have the CCW and DSP Hooked up..
Can anyone around New England hear me ??
My grid is FN42pb

73 and Happy Listening..

If you are interested in LowFer schtuff try 'LWCA' on your search engine to get
the LOWDOWN and other related files..

Hi, Roger.

I, too, am still quite enamored with homebrewing, modifying, and repairing equipment. I am in my 20th year as a licensed ham, and I have a 2-year degree in EE. I work as a computer programmer, pure software, so all of my EE work is at home, related to hamming.

I am a pure CW operator on HF. I love QRP operating, and I enjoy building QRP equipment from kits and magazine/book articles. I also like restoring "boat anchor" gear, especially old Heath gear. I have a well-stocked junk collection from all my years of doing this, and I have a network of friends who also have similar interests and well-stocked junkboxes that I can raid.

Yes, I think that we are a dying breed, for many reasons.

It is virtually impossible for even an experienced "home technician" like us to repair much of today's ham gear. I had the cover off my TS-870S when I first got it last winter. I took one look inside, and swore I'd never open it again! There's no way I'd attempt to repair it, should it ever develop a problem. Nearly all of today's gear is that complex inside.

While there is always another interesting project or two showing up every month in QST, 73, or one of the other journals, too many of today's hams have little or no electronics background, and many of the articles are of a higher caliber than a beginner would want to attempt. Over the years, a great many construction articles have been related to that other dying art, operating CW. Too few of today's hams have enough serious interest in CW, coupled with their limited technical knowledge, and that makes the old CW rig construction articles worthless. TNCs, ATV, digital stuff, DSP filtering, all are too technical for the beginner. Heck, some of that stuff's too technical for me too! Another problem is a lack of "elmering" by us old-timers (yeah, I know, I'm not really an old-timer by general standards, but 20 years qualifies me as one for the newbies). I try to "elmer" anyone who wants the help, and I know of some others who do the same. But there's sure not as much of it going on as there was ten, fifteen, or twenty years ago. What happened? We sit and complain about the no-code license, VE testing making it too easy to get a ticket, lack of technical knowledge, et cetera, then we sit back and do nothing about it. This could change, but will it? I'm not faulting the newbies. They come from widely varied backgrounds, most of which aren't related to electronics or communications. Nobody knows anything unless they are taught, right? WE need to do the teaching, or it won't get done. Used to be, you had to do your homework to get a ham ticket. We had to KNOW the rules, electronics theory, radio wave propagation principles, and such. We didn't have the question pool available to memorize. That isn't the case any more. You

really don't have to know anything except how to read and memorize things nowadays. I personally think that's a bad thing.

On the bright side, a local ham just built (from scratch!) a super-regen receiver as a project with his two young sons, ages about 7 and 5. They scrounged my junkbox for some of the parts, and bought the rest. Their receiver uses transistors and ICs, but it's still just as hard to tune and fickle to operate as the old two-tubers were. It warmed my heart to see this project go together. They built a wooden box with a Lexan front panel, so you can see all of the components. It's built point-to-point and it's ugly as sin, but it has that certain curious beauty about it, a beauty only a home-brewer can appreciate. (that's a shame)

Suppose the newbie finds a project that he/she wants to build. At least a lot of the projects these days use parts available at Radio Shack or from a mail-order supplier such as Mouser. But let's uppose that this project is not something from last month's QST, but instead is from an old ARRL Handbook from the 1960s. Where is that poor sucker going to find the old style parts to build that whoosy-whatsis? High-voltage parts, tubes, and other old-style parts are too hard to find, and when you do find them, they are way expensive. Too many of the "old timers" have passed on, and their junkboxes (which were filled with wonderful old parts that are now worth their weight in gold) were simply emptied into the dumpster once the commercially-made ham gear was sold off. The resources are drying up.

There's also this perception that anything that doesn't contain a bunch of ICs is not useful, so no one bothers. Hey, tube gear may be old and not sophisticated, but it still works. And, it's still fun to build, even just for the nostalgia value. The digital revolution has brainwashed too many of the new and prospective new hams. The desire these days is for more and more features, and the older gear, whether homebuilt or not, doesn't deliver this. I don't know how to change the perception. Maybe we can't.

I apologize for rambling on so.

Thanks for listening!

I believe the part that you are referring to was called a Byristor by CTC (Communications Transistor Corp.) I think the CTC Part number was BY-1. It is a diode with the construction of the base emitter junction of a RF transistor, and a resistor from the anode to the second terminal. It was intended to be used in the base bias network of linear amplifiers to temperature compensate the bias with the same characteristics a the RF transistors base emitter junction. Motorola application notes use the base emitter junction of a power transistor that is bolted to the heat sink to do the same job. I remember the device being discussed in a article in Ham Radio magazine in the 70's and in an issue of RF design magazine in the 80's. I hope this helps. Regarding converting the bias to class A It depends on the device, check the Motorola application notes for info on this topic. RCA had a good application note on the topic in there old RF power data book. The basic issue was hot spotting which is improved by emitter ballast resistors in the RF transistor. I suspect though that you will not get as much improvement as you hope going to full class A. I suspect that increasing the negative feedback and other distortion canceling techniques will give better results. I hope this helps

I owned a Swan years ago and as I recall the RX and TX share the same
VFO- a 13 Mhz VFO I believe they then tripled this to 39 and mixed it
with a 10.7 IF (the Swan 250 was slightly different IF as I recall).

Because RX and TX use the same VFO I am not sure how they could differ
in frequency by any significant amount. Have you put it in tune position
and placed a counter on with a dummy load to look @ TX freq?

Just some thoughts. Too Many years ago for anything more detailed.

73, Dale WA2YPY

Hello,
We have a GE Portamobile Radio on 49Mhz. Is anyone familar with
this radio? All we have is the radio on 49.180 Mhz and the AC
powersupply that clips on to the bottom. The radio does transmit 10
watts but we do not have a receive xtal. The model # is HN44LA833
TX data ET61A and RX data is ER43A. Any info would be appreciated.
Will the radio tune up on 6M? Does anyone have realigning
instructions? Copies of the service manual?

Thanks

Manufactures SHOULD hear what users think about their products. It helps them do better jobs.

In all fairness, manufacturers should be told directly first, and given an opportunity to address the concerns.

Things changes for the better more often when one gives feedback, good or bad.

> >- Use of 144Mhz is required.
> >
> Why? Did you get a license for this band?

Even with a licence, use of homing transmitters for this purpose in the 144 MHz band is not allowed in the Netherlands. Organized foxhunts are covered by the regulations, but this type of use of the 144 MHz band isn't. I don't expect any trouble if power is low and the duration of the transmission is short, but strictly spoken, it's not allowed.

As far as I know (but I am not sure of this) there are a few telemetry channels in the 27 MHz band which may be used for this purpose. The ISM band at 70 cm is also a possibility.

Still it should be no problem. A simple XO built with SMD components and encased in foam or something like that is inexpensive and can take an awful beating, provided the PCB has been soldered correctly. Power is also no problem, 10 or 20 mW should cover a 3 km area easily.

[Wildlife tagging transmitters]
> You may have more luck with those. Probably they have some acceleration
> robustness requirement. Otoh, the battery lifetime should be measured
> in months rather than minutes, so probably you could do with smaller
> batteries.
Wildlife taggers transmit short pulses (200 ms in a 2s period, for example) to conserve batteries.
You could conserve power by doing that with a rocket homing TX, and simplify the design and power consumption by using an unmodulated signal. It's a bit harder to find with a foxhunt receiver, but you could adapt your RX design...

Hi,

TIA for reading this. I have a dead Schottky mixer diode,
Mfg ALPHA Model DMF5139 that I need to replace. Can anyone cross
reference this to any other mfg's & part munbers? Does anyone
have a mailorder vendor who might be able to supply these?

Thanls again,
KO4LW

1725. Q. Unusual RF component in 100 watt 2 to 30MHz wideband linear

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-09 00:00:00 UTC
From: hill@rowland.org
Message-ID: <53g96m$bft@shore.shore.net>
Source record: 101900
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.equipment,sci.electronics.misc,sci.electronics.components

Can you identify an 4-terminal component called a ACR Z0-28F and looking something like a RF power transistor?

I just purchased two military 100 (200?) watt wideband linear "preamplifiers" (that's what they're labelled!) which seem to work fairly well. They work so well they burned out my 40 watt attenuator, forcing me to bring out my BIG loads! The amplifier uses a pair of MRF466 for the input and MRF429 for the output. These are "gull-winged" RF transistors with a bottom that reminds me of a TO-66 for transferring heat.

Anyway, for my application (flipping atom spins in a condensed-matter trap) I'd like to reduce the 3rd harmonic distortion of the amplifier. The amplifier has an external input for biasing the transistors toward class A operation. Each push-pull CE stage is base-biased with the above-mentioned unusual component, which has four terminals: the 1st one to ground, the 2nd to the two bases (bypassed with 22uF and via an rf isolating xfmr), the 3rd to a 200-ohm trimmer to the 4th terminal, which goes to the external connector for bias control.

With 0V to the external input, the amplifier draws no current. Applying +5 to +12 volts to the external biasing input changes the total current from to 1 to 4 amps, for example (while taking 0.5A on the control input). Although the unusual part is performing a "dc" function, it is manufactured as a high-performance RF part with 4 gull wings, just as the MRF466, and is bolted to the heat sink as well.

What is this unusual part and how does it work? Also, if I keep increasing the class A bias, at what point will I be in danger of thermal runaway and destruction? The amplifier's heat sinking is massive.

30 years ago, I was enamored by the prospect of soldering together a handful of components and ending up with a functional transmitter, receiver or some other magical electronic device. For me that love has yet to fade. Recently while discussing the world of homebrew with a ham friend, he challenged me to show proof that there is still a viable audience out there in the world of hamdom for material that introduces hams to the how and why of equipment construction and repair. Now since this is a subject that's near and dear to my heart (I think proof of ownership of a soldering iron and signal generator should be required to obtain a ham ticket - please don't flame me for that opinion), I naturally assumed the thing I like most about ham radio is popular with most other hams. After considerable thought, I'm not so sure. An unscientific survey of our local club, 40+ members, reveals that fewer than five do any work at all on their own equipment,much less any homebrew work! Checks with hams in other area clubs reveal a similar percentage of hams who still heat a soldering iron on a semi-regular basis. Blame unrepairable micro-miniature equipment, the impossibility of homebrewing gear that can compete cost or feature wise with the factory-built stuff, lazy hams or whatever you like. My question is this: Are we who enjoy the technical aspects of the hobby headed for extinction? What do you think?

Well, I guess you can count me amongst the doomed! While I do own a few "riceboxes" only one of them (a 2M HT) was bought new. All the rest were good deals because they had something wrong with them. Fix them up, and I'm a happy ham! (and a cheap SOB) The most recent was a 2 meter rig that was given up for dead because the mic cord was too long! (i.e. broken solder joint, shorten cord, resolder) I've been melting solder for much longer that I've been a ham, and I guess it just sort of carried over. I'm building QRP rigs now, made my practice oscillator out of parts from a toasted computer monintor, have electronic "carcasses" all over the basement just "in case" I might need the parts. Tough to explain to the YL.

I think most amateurs are content to be appliance operators and I have no problem with that. It is now much more of a hobby than a service, so whatever people enjoy doing with radio, they should do. Not that I don't lament the demise of the homebrewer. It's nice to run into one once in a while and not be stared at when you say something like, "Have you seen the spec's on the new low power 602's?".

Seems that anywhere the "suits" can make money, homebrewing starts to die off. Just look at what the no code tech licence did for big three in terms of two meter offerings. Before I get flames "I SEE NO-CODE AS A GOOD THING". Most all of the builders I meet anymore are into QRP or microwave since there isn't much chance you can outdo a mass produced HF rig and there are very few commercial offerings for QRP or uwave. Both appliance operators and homebrewers have their place, but I for one am much happier being one of the homebrewing dinosaurs.

I guess I could add that getting on the microwaves still requires homebrewing
in almost all cases. There is very little commercial gear available that is
intended for ham usage above 1.3 GHz. Compounding the lack of commercial gear
is the difficulty in getting test equipment inexpensively. As a beginning micro-
wave builder/operator, I'm finding the experience very similar to when I
first started in ham radio in 1971, when I built my first gear and was
not easily able to verify that anything worked. The best resources I've found
are other hams in the same area (I'm grateful for that!) who already have
gotten _their_ homebrew gear on the air. If you're willing to try several
hundred mile QSOs on milliwatt power levels with gear you build yourself and
carry around in your car, microwaves might be the ticket to the homebrew itch...

Hi Roger,

I still repair all my equipment, including the solid state stuff. I also still homebrew and experiment. It remains as much fun as it always was, perhaps even more, with solid state gear and qrp projects. We need to do more club projects, teach classes in our clubs and talk it up. Your post is a good start, and I hope a large number resolve, as I am, to become more active in getting others "hooked" on building, experimenting with, and repairing, equipment. One method would be for clubs to pool their resources and set up work areas so hams can experiment, test and do repairs.

I hope others will come up with more ideas, and will begin working through their local clubs to stimulate interest and encourage hams to put their theory to practical use.

Thanks for the stimulus!

73,
Jim - AD4VL

1735. Smart battery charging circuit???

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-09 00:00:00 UTC
From: ag121@torfree.net
Message-ID: <53gnl8$iru@news.inforamp.net>
Source record: 101910

Hope this isn't a dumb question!

I'm interested in a circuit to control the charging of a lead acid (ie car) battery. I use the battery as the power source for my packet station. It runs the radio & tnc continuously. The average drain is fairly low 1 or 2 amps, with peak load around 9A for transmit.

I have used a cheap car battery for this for a couple of years, but leaving a trickle charger connected almost all the time ended up wrecking the battery.

I am looking for a circuit that would:
a) turn off the charger when the voltage accross the battery terminals exceeds 14.4V,
b) turn the charger back on at a preset voltage - say 12V,
c) and disconnect the battery from the load if the voltage drops below a "fully discharged" voltage - around 11.4V

Has anyone any ideas on this? Thanks & look forward to your replies - here or via email.

Bryan

Check out the Motorola Application Notes dealing with the 100 Watt
Amplifiers. They may use a similar device in their design. My guess
is that the device is bolted to the heat sink to track the thermal
characteristics of the amplifier. A 100 Watt BJT amplifier needs to
have its bias circuitry carefully designed to prevent thermal run-away.
As the amp heats up I would bet that your device reduces the bias
current. I am assuming that the MRF429s are BJTs.

By the way, where can other people get ahold of such amplifiers

FWIW:

I peddle pieces/parts at hamfests. I notice that I have as many "young" customers as I do "old" customers.

As to the cause of the demise of "technically qualified" hams, I can suggest several reasons, most of which have already been posted. But, maybe the primary reason is the disappearance of Elmers, those "old timers" who took the time to tutor and coach newcomers to this hobby. Today, one studies a bit, memorizes some answers, passes the test, buys a HT, and becomes an instant ham. I am not critical of that approach to licensing but I do realize that it creates a different breed of ham.

I still tinker, repair, and brew a bit. And, I try to convince newcomers that there is some fun associated with such activities. While I can't claim to be an instant success, I have seen some of the new folks try.

If you've gotten away with connecting the input of a three-terminal
regulator directly to an automotive system you are lucky indeed!
Overvoltage protection and filters are often used to protect the
regulator from the dirty automotive power.

While it's true that you can't get an LM317 much below 2 volts --

WHAT USES LESS THAN 2 VOLTS??

It's simple enough to use a potentiometer as a voltage divider, and put
a voltmeter across ground and the wiper to read your extra-low voltage.

H-P makes some very nice programmable power supplies that go from
0 to everywhere...but I felt I was making a reasonable suggestion
with the LM317, because the requester said that the Radio Shack
adjustable supply was just fine. It's like $50; I assumed
the requester wanted a $5 solution. If this was not the case,
may I suggest the H-P Test and Measurement catalog? Should
be able to find something minimally adequate for less than $10,000.

Have a nice day.

> Are we who enjoy the technical aspects of the hobby headed for
> extinction? What do you think?

Y'know, I happen to think that Ham Radio never did have very many who could really build a rig. What has happened to this hobby is that it became much more popular thanks to the much derided Japanese electronics industry. But those who homebrew haven't disappeared, they've simply been outnumbered.

Second, the motivation to build gear isn't what it once was. I look at building/repairing your gear about the same way as most of us look at the shade tree mechanic of yesteryear. It really is more complicated now. Things like chips make construction somewhat easier, but the reality is that few homebrew radios can approach the low cost and high performance of most manufactured equipment. So you do it only because you like doing it. Those folks are very few and very far between.

It also isn't easy getting started. I have an EE from Johns Hopkins. Even that isn't really well suited for homebrewing. They don't teach this stuff anywhere. You sort of learn it by doing. And to be quite honest, I'm not really sure just how one is supposed to teach homebrew techniques. It is kind of like trying to teach reason. Or legislate quality (Yes, I mean ISO 9000!). People sort of get it or they don't.

That's a rough thing to say, but I don't know how to say it better.

Thankfully, there are perhaps as many people like this today as there ever have been. There just weren't very many to begin with...

How about a LN3914 , set up to read 10 to 15 volts in .5V steps ,in bar mode. take 2 of the outputs(14.5,11.5) to control a s/r Flip-flop ,controlling a SSR, or conventional relay, which controls the charger

Also , why not use deep cycle batteries (several hams in my area use golf cart batteries), they will take the cycling better than

Signals only go a couple feet and then disappear? Not here. Maybe to dissident signals in some country where the ruling hegemony would like the indigenous local people to disappear... like maybe Eastern Turkistan. Maybe there the lowfer signals go a couple feet before being "disappeared" by the organs of state security.

My own experience with lowfering includes hearing -- regularly -- the signals of two stations more than 30 miles south of my rather bleak (as lowfering goes) location. I'm right on the main drag between two concrete plants with a power distribution station (transformers &c) down the road about a mile or so. The cleaner's shop across the street has neon lights in the windows and the bank next door has those damn "bright as a sunrise on the moon" security lamps on 12 hours out of 24. Even with that junk around me, I can regularly copy YHS and one other guy (whose call I can't remember), both of whom are located at least 30 miles to the south. I have heard many whispers of other lowfer beacons, but not as regularly as these two.

And the Part 15 regs for the "medfer" guys (between 550 kHz and 1700 kHz) are just as draconian. Like I think it's maybe what, 8 ft of antoona and only 1 watt or something. If I can hear my own "wireless mic" on 1605+/- about a mile from my house, I'd bet that a real system (good ground, good antenna, efficient transmitter &c) would do better.

So there is something to trying out lowfering. If I had a better location for a transmitter (and certainly for a better receiver set up), I'd be a lot more activo than I am... which ain't that much. And on good nights in the winter, I can hear the heterodynes from what I presume are LW broadcast stations elswhere on this green planet of the clocks.

It's fun. It's weird. It ain't disappeared. It's science.

Water makes a fine dummy load. I have used it a number of times to
make very high power dummy loads.
Made some for 60kw hf transmitters at the Signal school when
it was here at Fort Monmouth. We used a fifty gallon drum or a
wood barrel and just fed the open wire transmission line right down
into the water with the wire going down about 24 inches or so.
Because they froze in the winter and you had to always check the
water
they were eventually replaced by fixed resistor types (very expensive)

Most tap water is conductive enough that you dont have to add any salt
(which wouldn't be good for the steel drum). Just adjust the spacing
of the wires and the length till you get a low or zero swr.

I made a small version here at home to fully load my 1500 watt
amplifier. I used a 5-gallon plastic bucket with a flat bar laid
across it which carried an SO-239 connector with the parallel wires
soldered to the back and spaced about 6 inches apart going down
into the water. Connected it through the swr/power meter and was in
business. If you have trouble getting it to take the load make the
wires closer or add a little salt (only a tiny pinch is usually needed)

For a temporary load it works fine.

Well, Roger, I think we may be a dying breed. Homebrewing and repair seem to be, at best, a niche interest among today's hams. A few reasons come to mind:

-- The growth in amateur radio today is in the Technician ranks. Until or unless they upgrade to operate on the HF bands, there is little homebrewing to be done. Most gear is readily available in plug-and-play mode, and conversion of surplus commercial equipment may be as close as many get. I do applaud Ten-Tec for introducting kits for VHF transceivers.

-- The demise of Heathkits is certainly a factor. While it may be argued that this is really assembly as opposed to homebrewing, the satisfaction of powering up a Heathkit and putting some mileage on something that one had a hand in making operable is still there.

-- As you pointed out, complexity of modern ham gear is a factor also. Most hams today don't own/can't afford/can't operate the sort of test equipment needed to service modern, commercially-available equipment such as produced by Icom, Kenwood and Yaesu, so it's back to the factory when they require service. I can remember that the instruction manuals for my Drake R-4/T-4X twins (which I still own and operate) not only had schematic diagrams, but also had alignment instructions. Only a VTVM and an RF Signal generator were required to perform this task; instruments that were common in the ham shack back in the 60s, when I got my General.

As an aside to the complexity issue, here's another problem: some of the newest and best HF transceivers present quite a learning curve, just to operate. When our club bought a new Icom IC-706, one of the problems we OTs discussed was the amount of work necessary to get it up and running. I'm not knocking Icom here, but someone pointed out the complexity of operation of the Icom versus some older Collins and Hallicrafters gear that had been donated to the club by the widow of a SK. On older equipment, most of the controls were located on the front panel, and had similar or identical names even from one brand to another. This is not an insignificant point, when you consider operating Field Day or any other contest, where there are numerous brands and models of transmitting and receiving equipment in use.

We can use the amount of discussion on the rec.radio.amateur.homebrew and the soon-to-come rec.radio.amateur.boatanchors newsgroups as an indication of the state of the homebrew/repair art.

One very avid group of homebrewers and assemblers today is the QRP crowd. I had the pleasure of meeting the famous Zuni Loop gang before Field Day this year, and almost everyone had a project to show. One of the recent projects involves building a 250-mw 40m CW transceiver, all of which fits

into an enclosure the size of a sardine can.

While I tend to think true homebrew is becoming a lost art, there still is hope for those of us who do like to build gear. I have had no electronics training, except for watching my father build Heathkit projects when I was young. I think the major problem is that back in "those" days, build your own gear was necessary because the gear was not available. As it was stated, homebrew gear does not come close to the features of the import gear. Without the need to build your own, we new hams are not as motivated to learn how to build our gear, then add in the problem of where are we going to go to learn it. I once saw an add for video tape electronics instrustons in a magizine. I been looking for several months trying to find it again, but no luck. Guess there wasn't a market. So we new hams are stuck to tread on our own. Playing doctor on todays gear can be very expensive. I do enjoy the kits still available. My first kit was the Heathkit Weather Station. At that time it was a $650 gamble. That was a lot of money to spend to take a chance of watching it go up in smoke. As it turned out, it worked. It reflects the quality Heathkit but into the instruction manuals. Its been 8 years and its still going. While I build several of the $10 to $20 kits from Ramsey, I am sorry to say,I still do not have a complete understanding of the workings. I am currently build the 2 meter radio kit from Ten-Tec. It was featured in the August issueof 73 Amateur Radio Today magazine. It has shades of Heathkit all over it. And at $200, not a bad deal. I hope other new hams discover the fun of building you own, even though it not true homebrewing.

> Who can help me out.
> 73 Teun, Pa3fvw.

The RLS135 is made by Rohm Co., LTD. They characterize it as a band switching diode. It is designed for low high frequency impedance and "small in-terminal capacitance". It's specifications are

P 150 mW
VR max 35V
Io 100 mA
Tj max 150 C
Tstg -55 - 150 C
VF max 1.0 V @ 10 ma
IR 100 nA @ 20 V VR
CT 1.5 PF @ 10 V VR, 1 MHz
rF 0.6 ohms at 10 mA, 100 MHz
Package LL-34 This is cylindrical glass package for surface mounting.

As for a replacement the Motorola MPN-3404 PIN diode is a possibility but I am not sure if it has a low enough on resistance and a longe enough carrier lifetime for HF applications. I hope this helps

1759. Help with Icom IC-22S service

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-09 00:00:00 UTC
From: tswisher@freenet.columbus.oh.us
Message-ID: <53guvt$c88@login.freenet.columbus.oh.us>
Source record: 101934

Hello all.

I just picked up an Icom IC-22S free from a friend. It does not work correctly but the price was right. If I can get it working it would be and ideal rig in the shack for communicating on a few specific frequencies.

He did not have a manual with the radio, and I don't have a service manual (nor do I know if they can still be obtained; the Icom tech support line is swamped). Can anyone give me a few pointers as to common problems with this particular radio?

Problems noticed so far:

1. No RF output that I can see, although the transmit light does light up.
2. Very little audio on receive and no squelch action.
3. Unknown if the diode matrix and it's associated circuitry are functioning.

I don't have any idea what frequencies are in the radio right now. I've not had the time to go through and decipher the diode positions to figure it out.

Please reply via e-mail to tswisher@freenet.columbus.oh.us or post on the group.

Thanks in advance for any assistance.

> capacitor and if it is connected in paralell or series.

> 73 + Good DX + Good Contest !

Several points:

1. If you buy their Icom adapter cable, it already contains the capacitor.

2. A number of hams have found that the Heil mics don't have enough gain to drive Icom rigs, which expect preamplified microphones. The newer Icom rigs seem to be more tolerant, but expect to either (a) leave the speech processor on and keep the gain turned to max, (b) modify your rig so it requires less gain, or (c) build a preamp of your own.

If you ask Heil for information on this subject, they'll send it to you. Expect a certain degree of editorializing on Icom rigs! The Heil folks seem to have strong opinions. I just checked my copy and the IC-725 isn't explicitly mentioned.

I bought an HC-4 this summer for my IC-730. It definitely needed a preamp. I ended up building a single-FET preamp based on a schematic sent to me by Heil... they had received it from an Icom owner, who had in turn gotten it from Icom. It makes the HC-4 usable, but I still need to keep the gain at max and the speech processor on. I still can't drive the rig as strongly as with my Icom mic, and I frankly think another 10 dB would be better.

Heil is considering marketing a preamp for this purpose, but they aren't ready to commit to it yet.

There were a number of messages on the subject over the summer, some in response to my post in rec.radio.amateur.equipment. If you do a Deja News search on Heil and Icom, you can see other peoples' opinions.

The Heil mics have a great reputation, and I'm pleased with mine--I just wish the Heil folks would come up with a better solution for us (older) Icom rig owners.

>
>WHAT USES LESS THAN 2 VOLTS??

Tunnel diodes crank at 100 mV drop - but I just sold all mine.

Sometimes it's nice to gently power something up - if you have something put in the socket backwards you find out with the current draw going through the roof with 1 v applied - and then you switch the power leads, and all is well. 2 V can be enough to smoke some things.

My power supply goes down to zero,and I use this feature all the time. But there's a cheat - it gives -15 V also, so there's a nice way to pull the ground pin of the regulator below ground, so it can deliver a nice, stiff ground, or thereabouts. For a car-battery-only system, this would need an explicit voltage inverter (like an ICL7660 or 7662).

Maybe a single-supply opamp, and a power FET? It would become high impedance down at ground, which isn't great, but it's still a $5 solution, at least - $10 tops, and could get pretty close:

He wanted schematics -

+ battery terminal -> fuse -> + 12 V

- battery terminal -> ground

50 k pot between +12 and ground. Wiper through 100 K to +input (pin 3) of single-supply opamp

Power FET drain -> +12 V
Opamp output (pin 6) -> 1 K -> gate of FET
Source of FET -> 100 K to - input (pin 2) of opamp, and also directly (no 100 K) as Supply OUTPUT
heat sink for FET depending on current draw - beware case of FET will be at +12V - so heatsink will need insulation either between it and the FET, or between it and the rest of the world.

anti oscillation: ~500 pF pin 6 -> pin 2 - maybe need more
opamp power: pin 4 = ground, pin 7 = +12 V
10 uF between pins 4 and 7, observing polarity.

FET: $2. IRF 511 (radio shack)
Opamp: CA3140, $2 ish - don't know if RS has these
pot: ten turns is nice: $4; 1 turn works: $.50
resistors, caps, heat sink
fuse holder - $0.39

car - Honda Accord - $14,499.00 (includes battery)

I am attracted to the possibility of passive radar.
There was an article in UK Electronics and Wireless World some years
back that involved picking up a direct radar pulse , synchronising your
own receiver from this and then processing the returns. Such a system
seems fairly uncomplicated.
An alternative requiring some processing power and two or more antennas
would employ one or more TV station signals. The system could be
operated like a parabplic mavigation system or TV modulation employed to
to determine distance (delay of shadow).

I've built both the TAC-1 and ARK-4 kits for 40 meters. Both are
excellent. The ARK-4 is a little smaller and draws less current on
receive but uses thumb-wheel switches for tuning. If you are truly
backpacking then you might want to consider the ARK-4, otherwise the
TAC-1's knob tuning is easier to use.

No. Highspeed modems talk to eachother at connection setup, and measure
the line characteristics to compensate for frequency and phase characteristics.
This is the warbling noise that you hear before CONNECT appears.

So, you can only use a highspeed modem on radio (I suppose that is what
you are after) when the radio path is fullduplex so the modems can hear
eachother all the time. And even then it probably won't work too well,
because a radio path has distortions (due to multipath, changing propagation
etc) that a telephone modem is not designed to cope with.

The QRP folks are almost certainly the most homebrew-oriented hams today.
Some of the journals, most notably SPRAT (G-QRP Club) are packed with
homebrew ideas and projects. But this is changing rapidly. An experience I
had at Dayton this year was enlightening.

At the Dayton QRP banquet, the MC said it would be interesting to know what
kinds of rigs people were using. He then asked how many people were using
the NorCal 40, HW-8, and so forth, naming each commercial rig or kit in
turn. (There was quite a list.) Finally, he asked if he had forgotten any
types. I meekly mentioned "homebrew". He hadn't thought of asking! Out of
150 or so people in the room, a handful (fewer than 10) raised their hands.

That evening or the next there was a judging of some homebrew rigs, and
several were beautiful or downright ingenious. But homebrewers are in a
large minority even among the QRP crowd -- in the U.S. at least.

No. Highspeed modems talk to eachother at connection setup, and measure
the line characteristics to compensate for frequency and phase characteristics.
This is the warbling noise that you hear before CONNECT appears."

Good point. So a forced connect speed does not preclude this negotiation?

Is there not some test mode with which the modulator can be used at high speed
without detection of remote carrier and negotiation?

" So, you can only use a highspeed modem on radio (I suppose that is what

Agreed. However, I am thinking of using a stable, high quality but unidirectional voice
(or wider) channel.

Hello,
We have a GE Portamobile Radio on 49Mhz. Is anyone familar with
this radio? All we have is the radio on 49.180 Mhz and the AC
powersupply that clips on to the bottom. The radio does transmit 10
watts but we do not have a receive xtal. The model # is HN44LA833
TX data ET61A and RX data is ER43A. Any info would be appreciated.
Will the radio tune up on 6M? Does anyone have realigning
instructions? Copies of the service manual?

Thanks
AB5LG

To them what's been talking about this, I agree. Homebrewing stuff is slowing down. It goes hand in hand with the growing concensus that most American band use has devolved to power contests (what we in the over-powered "Ohio Valley Teratology Net" used to call "horse-races"), bitter abusive disputes and positively paranoid rantings that come close to being personal broadcast yellow journalism. But that's another topic.

I know a bunch of lunatics who still like to build or at least discuss circuit design and the tribulations of making stuff what starts out as metaphysics into physically tangible stuff on the bench. Most of 'em are either tube-heads (as in: people who still like warm boxes of stuff with tubes inside) or they are QRPers, or they are something in betwixt. Me? It's a little of both.

On one side of the building fence, there's a lot of nostalgia. We bemoan the demise of Heath and the japanization of Drake and the disappearance of Collins. We want to have the boxes that we had when we were kids. We even build boxes for our own kids (like the revamped MRL #2 xtal set that I built for my eight-year-old). But we build stuff, and often enough, repair stuff what was munged by the ham-fisted (and that "ham" as in "as big as a Virginy-cured ham [as in slab of meat about the size of a sumo wrestler]).

On the other side of the fence, there's a lot of proof of viability. We wanna show our families or friends or even just ourselves that we can still make stuff that works, even if only in a nominally successful way. It's the creativity complex, perhaps. But we have to have the iron on and the desk cluttered with boxes of poorly sorted excess junk: screws and washers and diodes and caps all thrown into various small boxes, ice-cube trays and plastic sort-em-drawer sets screwed haphazardly to the shack walls. Leonardo and Durer live inside us. We gotta make something out of all this crap or we don't exist. Kinda like the Russian proverb, only this time it's not a matter of eatin' but more a matter of just being.

And those of us old enough to remember the shock of Sputnik do indeed have sometimes monumental collections of excess baggage in parts and knobs and pieces of equipment that no longer exist. We know about Atwater-Kent from our parents' stories while our children don't even know what a phonograph or record player is. We figure that we're keeping history alive. And maybe we are. Which makes it all the more essential that we somehow manage to leave our junk boxes behind with the request that they end up in the hands of some one -- one solitary remaining someone somewhere somewhen --

who will say "Holy shit, will you look at these tubes! Man, I gotta make somethin' out this!"

That's all we got, brethren and sistern. Somehow we gotta pass it on. Otherwise Radio Shack will determine the mental acuity and creativity of our grandkids and their grandkids and the Handicapper General will indeed have won the day. The Marching Morons ain't that far behind.

Build! Kto nye stroit' nye byt'/Den som bygger inte er inte...

>do applaud Ten-Tec for introducting kits for VHF transceivers.

I think many of today's Techs (and other classes) aren't homebrewing.
Part of the reason for that is many of them are new to amateur radio
and aren't quite sure of their skills and knowledge yet, IE they're
a bit intimidated by the thought of building their own equipment. And
part of it is the wealth of available off the shelf equipment, so there
is no pressing need to build. But I take issue with the idea that you
must be on HF to homebrew.

Homebrewing becomes easier as you go up in frequency. There are
several good reasons for that. Stripline circuit boards remove
many of the stray problems, eliminate messy discrete inductors,
and favor the much easier to use SMD parts. Harmonic suppression
becomes easier as well. And most beginning VHF+ projects are FM.
That simplifies many things. The IF operates with hard limiting,
so AGC systems aren't required. The demodulators are nearly
foolproof, and easily tuned up by ear. Frequency stability
tolerances are relaxed. Etc.

And there are many good ICs which offer complete FM IF subsystems,
complete demodulators, etc. And there are good packaged mixers,
cheap and stable MMIC gain blocks, and even a number of electronically
tunable LO sources. On the transmit side, there are hybrid PA modules
available that are stable, 50 ohms in and out, and offer power outputs
in the 5 to 50 watt range when driven by low level inputs.

I build a lot of quick projects to test new ideas, and it is much
easier to do so at VHF+ than at HF.

>shack back in the 60s, when I got my General.

Actually, today's radios are somewhat easier to service than the old belchfire models. Certainly they are *safer* to service. You can't just look to see which tube isn't glowing, but then tubes failed often, transistors and ICs seldom fail. When they do fail, it is usually obvious what's happened by the behavior of the radio. Many of today's radios fail, when they do finally fail, due to passive component failures, especially intermittant problems. Those were a bear to track down in the old belchfire radios, and they still can be in the newer radios, but liberal use of component cooler and heat guns can find them fairly rapidly.

You don't really need elaborate test equipment. The most important piece of test equipment is between your ears. Beyond that, a DVM and a signal source are still the basic tools. A logic probe can be handy too, but usually not essential. Sometimes a scope is a very nice thing to have, but it was in the old days too. It's just that back then many of us couldn't afford one. Today, there are inexpensive imported scopes available, and the surplus market teems with high quality scopes we would have killed for in the old days.

A power meter and a dummy load are handy things to have for transmitter servicing today, but they were back in the belchfire days too. The only tool many of us consider a necessity today that was almost never seen in the old days is a spectrum analyzer. In the old days, we just *hoped* our signals were clean. Today we can look and see that they are clean. Again, the surplus market can supply us with instruments we couldn't even have dreamed of owning in the old days. But we can do without one, and just hope our signal is clean, like we did in the old days. (I don't recomend that, but we can.)

>As an aside to the complexity issue, here's another problem: some of the

>you consider operating Field Day or any other contest, where there are
>numerous brands and models of transmitting and receiving equipment in use.

I'm frankly flabbergasted by this comment in reference to the IC-706. In my opinion, the IC-706 is the most intuitive and operator friendly radio I've ever owned. It takes about 5 minutes to learn to navigate the menus, after that you can toss the instruction book (even without the initial resort to the instruction book, you can quickly figure things out). Every feature is clear and basically self-explanatory.

That's certainly not true for some other radios. I spent two hours, manual in hand and salesman by my side, trying to make the FT-8500 do a simple thing the manual says it'll do. We couldn't figure it out. We called the factory for support. They tried to talk us through it, and it became obvious that *they* didn't understand how to do it either. (We found out later that the manual was wrong, the firmware version in the radio we had didn't support doing what I was trying to do. Arrrgh!) Some of the Standard radios have menu systems which are byzantine too. And I don't even want to get into the bizzrre idea of a user interface that Kenwood has. But the IC-706 is a dream to operate. Everything is very clear, intuitive, and easy to access.

OTOH, I defy you to set the carrier balance and sideband suppression on a HT-37 belchfire radio without resort to the manual (and plenty of patience). That's something you found yourself doing *a lot* on that radio. Tuning up a B&W 6100 *properly* for the first time without resort to the manual is likely to cause great frustration too. The old radios each had their own foibles you had to learn. I ruined a set of finals in a TR-3 before I caught on to the proper way to tune one up. Modern radios won't let you do that. They'll protect themselves if you try to do something stupid.

And nearly all of it is very simple to repair. It doesn't matter how many parts are inside, you're only going to have to replace the bad one. Before you even remove the cover, you should be able to narrow the problem down to one or two functional blocks from the behavior the radio is exhibiting. All the other parts can now be ignored. A quick check or two will narrow the problem down to one functional block. A couple more checks and you're down to only a few components as possible failure points. Then straightforward component level troubleshooting will identify the faulty component. Simple.

Many of today's radios have gone to surface mount parts, and that makes repair a lot easier. You only need to be able to get to one side of a circuit board, so you often don't have to disassemble the radio very far in order to replace the bad part. SMD has made the repairman's job much easier.

>While there is always another interesting project or two showing up every

>stuff's too technical for me too!

You're right that many of the old projects revolved around CW transmitters, and not that many people are interested in that anymore. But the other stuff isn't too technical for the beginner. Most of the high tech is safely tucked *inside* the ICs. So the beginner can treat them as functional blocks with a given transfer function. That makes building easier, not harder.

>Another problem is a lack of "elmering"

>need to do the teaching, or it won't get done.

That's right, If we want people to build, we have to show them how to
do it. Of course it would be helpful if we've kept up with technology
ourselves and actually know how to do what the person we're teaching
wants to do. People are capable of learning many things on their own.
They don't need formal teaching to understand modern electronics. The
library and bookstores are full of texts from which they can learn
that. But some of the *craft* skills needed for home construction are
best learned by example. There are many tricks of the trade that ease
home construction. We need to show these to the beginning builder.

>Used to be, you had to do
>your homework to get a ham ticket. We had to KNOW the rules, electronics

>really don't have to know anything except how to read and memorize things
>nowadays. I personally think that's a bad thing.

It's not really that different from the old days. And frankly, what
you need to know to pass the exams, then and now, is woefully inadequate
to prepare you to be a builder. Passing the exam merely gives you license
to begin learning how to do that.

Ugh. A superregen. I hope it doesn't turn them off to building. They
might get the impression that that's the best they can do at home and
turn back to commerical equipment. (I'm not knocking their project if
what they wanted was to find out how bad the old circuits were. I
just hope that they know that for a similar parts count they can make
a much better radio today.)

Actually, I hope we can't. The newer designs are better. They're easier
to build. They have better performance. And the parts *are* available.
Reliving the old days may be nostalgic, but it isn't the best way to
approach most building projects today. There's a reason the old parts
are hard to find, they don't do the jobs we want done as well as modern
parts can do them, so they've fallen out of use.

> I am still looking for help in forcing a simplex high speed connection with Hayes
> AT compatible (or other) modems.

If the Hayes has "FAX" modes, try them. Like V.29 or something. I've
done
amateur radio links
using v.29 (which is the standard 9600bps mode) and it works fairly
well.
You'll need to use fairly long txd's.... something on the order of 400ms
due to the train sequence it sends, but other then that it works well.
You will need to make sure you audio is not clipping however as V.29
is 16 level QAM. The train sequence is (I think) about 250ms plus
another 150ms for the radio to stabilize. There is a fast train mode
you can use which is only 50ms long.

V.29 is a half duplex data modem standard. Center carrier is
1800hz. Some of the results I had got written up in QEX and
TAPR PSR a number of years back. Also, the Japanese have
done some work with this as well. They (I think) were using
the Rockwell chip set... I was using the Yamaha chip. I little
write-up is on the PRUG homepage (sorry, don't know the URL).
They (the Japanese) have also done some work with V.27 (7200bps)
which is a little more robust in a radio enviroment then V.29.

I've not tried the 14.4 fax modes.

On slowly "fading" channels, you shouldn't have much problem assuming
you re-train
frequently. Actually, its been my experince that a radio channel is

better in most
cases then a telephone channel. Now, I am talking about a properly
engineered link
with clearences in the fresnel zones. This of course is a VHF/UHF link,
not HF or
some "HT" style rubberduck packet station.

Good luck

I'd also have to include the technology shift from point-to-point
wiring to printed circuit boards.

This changed the relationship of kit-building to homebrewing. In the
point-to-point days the functional relationships of all the components
was pretty exposed and clear. Homebrew gear and kit gear looked very
very similar except for the quality of the sheet metal and paint job.

This all changed with the intro of PC boards. Kits and homebrew
diverged. The direct relationship of component to function was hidden
and homebrewers simply couldn't fabricate PC boards *easily*.
Still can't, but at least design and layout is a lot easier now.

Unfortunately, this has a big effect on people getting started -
In the old days, beginners could learn by building a Heathkit, then
homebrew something similar.
Parts were readily available and fabrication took nothing more than
a soldering iron and rat-tail file.

This is still true for some accessories and for vintage homebrewers
(except for parts accessibility) but you can't get into
homebrewing as easily as before. New components require PC boards and
PC boards aren't easy to get into.

All this, of course in addition to the trend to disposable consumerism.

In one of the Gunnplexer "CookBooks" there is a section about making a Gunnplexer into a radar unit. I believe it chirps it as you suggest. Supposedly you could get good reflections off nearby rain bearing clouds. Or so the author claimed.

Not sure if the rules make this legal, but no reason you can't use "radar" on the lower bands as well. What you lose in resolution you make up for a bit easier time doing things, at least to start. In fact, I think the British used a low VHF band in there first radars.

'DSP' techniques really can help us here.... might be a good front end for a radar unit that talks to a PC based display terminal.

Another neat thing amateurs could do is put cube reflectors on there balloon launches. Or mapping the ionosphere.

Back in 1971 or so, after I played with the classic LC tuned circuit-long wire-antique earphones-diode thing, I homebrewed a superhet AM radio using transistors, and various parts scrounged from the junk box. Designs were mostly copies of other radios, but different sections came from different source radios. And it actually recieved some stations when I first fired it up, before alligning it (I lived 6 miles away from a 50KW Am station on 770KHz (WABC)). Also tried to build a copy of the 5 tube "All American" AA% radio, but that didn't work. Think one of the parts I scrounged (IF transformer?) was bad. My father thought a superhet might be too ambitious, but Iwanted to do a 'real' radio.

Right now, I'm playing around with an old early 60's AA5 AM tube radio, substituting sub-mini "pencil" vacuum tubes for the standard 7 pin tubes (using a heater voltage transformer to run the 12V and 6V heaters). No 'real' reason, other than making a radio that might have been manufactured if semiconductors had not been invented, and sub-mini tubes being the "next generation" of tubes for AM radios (assume that mass production of pencil tubes would get the cost down). Having fun. Still trying to design a triode osc and pentode mixer stage to substitute for the 12BE6 pentagrid converter. triode oscillates fine, mixer output is a weak signal, weaker than the 'BE6. Will probably learn about some subtile things of superhet design.

> This is the warbling noise that you hear before CONNECT appears."

>Good point. So a forced connect speed does not preclude this negotiation?

No, it doesn't. Speed negotiation is only a very small part of this
process. The remainder is referred to as "training" and needs to be done.

>Is there not some test mode with which the modulator can be used at high speed
>without detection of remote carrier and negotiation?

Training is always required in these multi-phase multi-level modulation
schemes. Even FAX modes, which are largely unidirectional, use training.
A slow (300 bps) fullduplex negotiation phase is used to coordinate the
training, the remainder of the transfer is unidirectional.

>Agreed. However, I am thinking of using a stable, high quality but unidirectional voice
>(or wider) channel.

To use standard telephone modems you will need a backward channel.
When you design everything from scratch (or: at least the operating firmware)
you might be able to come up with some protocol that does the training
with only a single direction.

What you say below is the truth about the current state of the US in general.

EG: I have a TV vintage 1985 that was hit by a lightning surge, and it fried parts of the front end. I took it apart, replaced the power supply stuff, other normal parts and traced to a bad chip. I called RCA, and they said that it was a custom chip, and that you cannot buy it anymore. Now I have a big hunk of junk for the garbage pit. It's not my idea of conservation. I also have a VCR that has a motorized loading mechanism that is no longer available. What can one do?

It's typical of todays consumer equipment.

I must say that I also have a really old TV that was also hit. I have schematics, and you can still get parts for it! I think that the way to go now is to buy old gear, as you can fix it when it fries!

We all know that the data rate on "standard" ethernet is 10Mhz, and with modulation of the data, the highest frequency used is 20Mhz. Given the fact that I have a spool of a few feet of nice 10-BASE-5 ethernet coax (yellow double shielded stuff) a few questions:

1) How good is it for VHF services (2 Meters??)
2) Loss figures??
3) Has anyone used it for this??

Any other comments...

Thanks

I have wood siding on our newly acquired house and I will be drilling a 1 1/2" hole through the siding and attatching an electrical "LB Box" to the outside of the siding and running the coax into the house. Then I will be mounting an electrical junction box in the wall (it will basically look like a box that would hold two regular electrical outlets, but has a solid metal cover on it that will be drilled and have 4 UHF or "N" bulkheads {Barrel connector with threads all the way so it can but fastened with nuts on both sides of the metal plate] on it with jumpers of coax running to the rigs. Sounds complex, but just take a visit to a building supply store and look at all the electrical stuff and you will get lotsa good ideas. Good luck! 73, Scott, N0EDV...The voice of Vernon County (Wisconsin)!

I have never operated myself, but many people have worked several hundred miles under ideal conditions. I recall one fellow claimed 750 miles. There are a number of beacons operating more or less continuously. Listen around and if you hear any CW identifiers, email me. I have a list and will look them up. Typically, they use their initials or the suffix of their ham calls.

The MRF466 is an NPN BJT rated for 40W (PEP) up to 30MHz. The
MRF429 is an NPN BJT rated for 150W (PEP) up to 30MHz. These are
both 28V devices.

>the control input). Although the unusual part is performing a "dc"
>function, it is manufactured as a high-performance RF part with 4 gull
>wings, just as the MRF466, and is bolted to the heat sink as well.

The unusual part may be a combination DC bias network (a diode
intended to match the characteristics of the RF B-E junction) and
RF feedback network for gain stabilization. Or something.

One area of homebrewing that should never die is building amplifiers. No micro-miniaturization here... big, hefty parts are the rule. A 1500 watt beauty that you built yourself will be a source of pride for years to come. Take your time and do it right, both mechanically and electrically, and you won't be sorry, I promise!

If this is what is commonly known as "thinnet" coax for ethernet, it is
RG-58. Very lossy at 2M.

I finally decided to read one of these articles in an internet
newsgroup describing how to make $50,000.00 in only one month from
a $5.00 investment.

Of course I thought this was rediculous ,or some type of pyramid.
I talked it over with my family, an attorney, and my friends, and
they all agreed it was some sort of scam.I hate scams because
usually someone gets burned, and I didn't want it to be me!
I blew it off for a few weeks then saw another one in a
newsgroup I go to alot and thought, "Maybe this is legitimate!".
Besides, whats $5.00 , I spend more than that in the morning on
my way to work on coffee and cigs for the day.

Well, two weeks later,I began recieving money in the mail!
I couldn't believe it! Not just a little , I mean big bucks!
At first only a few hundred dollars, then a week later, a
couple of thousand , then BOOM . By the end of the fourth
week , I had recieved nearly $47,000.00. It came from all
over the world.And every bit of it perfectly legal and on the
up and up. I've been able to pay off all my bills and still had
enough left over for a nice vacation for me and my family.

Not only does it work for me, it works for other folks as well.
Markus Valppu says he made $57,883 in four weeks. Dave Manning
claims he made $53,664 in the same amount of time. Dan Shepstone
says it was only $17,000 for him. Do I know these folks? No,
but when I read how they say they did it, it made sense to me.
Enough sense that I'm taking a similar chance with $5 of my own money.
Not a big chance, I admit--but one with incredible potential, because
$5 is all anyone ever invests in this system. Period. That's all
Markus, Dave, or Dan invested, yet their $5 netted them tens of
thousands
of dollars each, in a safe, legal, completely legitimate way.
Here's how it works in 3 easy steps:

STEP 1.

Invest your $5 by writing your name and address on five seperate□
pieces of paper along with the words:
"PLEASE ADD ME TO YOUR MAILING LIST."
(In this way, you're not just sending a dollar to someone; you're
paying for a legitimate service.) Fold a $1 bill, money order, or bank
note inside each paper, and mail them to the following five addresses:

1- Philippe
2104 De Mexico

Chomedey, Laval
Quebec, Canada
H7M 3C6

2-. Herta Dunbar
1200 Oldfield Point Road
Elkton, Md. 21921

3- John Kelley
P.O. BOX 4363
Brockton, MA, 02403-4363

4- Colleen Walker
250 Cassadnra Blvd #428
Toronto, Ontario
M3A 1V1
Canada

5- Simon Dominguez
Flat 3, 27 Market Place
Burslem
Stoke on Trent
Staffordshire
UK
ST6 3AG

STEP 2.

Now remove the top name from the list, and move the
other names up.This way, #5 becomes #4 and so on.
Put your name in as the fifth one on the list.

STEP 3.

Post the article to at least 200 newsgroups. There are at
least 17000 newsgroups at any given moment in time.
Try posting to as many newsgroups as you can.Remember
the more groups you post to, the more people will see your
article and send you cash!

STEP 4.

You are now in business for yourself, and should start seeing
returns within 7 to 14 days! Remember, the internet is new
and huge. There is no way you can lose.

Now here is how and why this system works:

Out of every block of 200 posts I made, I got back 5 responses.
Yes, thats right,only 5. You make $5.00 in cash, not checks or
money orders, but real cash with your name at #5.

Each additional person who sent you $1.00 now also makes 200
additional postings with your name at #4, 1000 postings.On

average then, 50 people will send you $1.00 with your name at #4,....$50.00 in your pocket!

Now these 50 new people will make 200 postings each with your name at #3 or 10,000 postings. Average return, 500 people= $500. They make 200 postings each with your name at #2= 100,000 postings=5000 returns at $1.00 each=$5,000.00 in cash!

Finally, 5,000 people make 200 postings each with your name at #1 and you get a return of $50,000 before your name drops off the list.And that's only if everyone down the line makes only 200 postings each! Your total income for this one cycle is $55,000.

From time to time when you see your name is no longer on the list, you take the latest posting you can find and start all over again.

The end result depends on you. You must follow through and repost this article everywhere you can think of. The more postings you make, the more cash ends up in

your mailbox. It's too easy and too cheap to pass up!!!

So thats it. Pretty simple sounding stuff, huh? But believe me, it works. There are millions of people surfing the net every day, all day, all over the world. And 100,000 new people get on the net every day. You know that, you've seen the stories in the paper. So, my friend, read and follow the simple instructions and play fair. Thats the key, and thats all there is to it.Print this out right now so you can refer back to this article easily.Try to keep an eye on all the postings you made to make sure everyone is playing fairly. You know where your name should be.

If you're really not sure or still think this can't be for real, then don't do it. But please print this article and pass it along to someone you know who really needs the money, and see what happens.

REMEMBER....HONESTY IS THE BEST POLICY.YOU DON'T NEED TO CHEAT THE BASIC IDEA TO MAKE THE MONEY! GOOD LUCK TO ALL,AND PLEASE PLAY FAIR AND YOU WILL WIN AND MAKE SOME REAL INSTANT FREE CASH!

*** By the way, if you try to deceive people by posting the messages with your name in the list and not sending the money to the people already included, you will not get much. I know someone who did this and only got about $150 (and that's after two months). Then he sent the 5 bills, people added him to their lists, and in 4-5 weeks he had over $10,000!

TRY IT AND YOU'LL BE HAPPY!!! :o) !!!!!!!!!!

Source record: 101878

On October 12, 1996, the Palo Alto Amateur Radio Association (PAARA) will hold its 45st annual auction and flea market at the San Mateo Shriners Center, 1925 Elkhorn Court, San Mateo, CA. Doors open at 7:30 A.M. and the auction will start around 9:30 A.M.

Ham radio gear, electronic parts and test equipment is likley to change hands at bargain prices. Raffle prizes will be offered and coffee & donuts will be served. All in all it will be a lot of fun for those of you who have the post Foothill Flea Market blues.

Flea market table space is available at $10 per table. Auction charges are 10% of the sales price (buy-back subject to $5/max. charge per lot). Equipment donations are welcomed by the club. Proceeds benefit PAARA.

Directions to the Shriners' Center. From HWY 101 or 280, take the HWY 92 to the El Camino Real South exit. On the El Camino Real travel to 20th Avenue, where you'll turn right. One block and you'll see Elkhorn Court. Talk-in frequency is 147.45 simplex.

Please, note the location this year ... it is in San Mateo. See you there.

1797. HF power amplifiers

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-11 00:00:00 UTC
From: lbc@senet.com.au
Message-ID: <53l9jr$et2@highlander.senet.com.au>
Source record: 101785

Hello all...

Can anyone help with a circuit for a HF power amplifier (the so called "linear") that has 4 output transistors of the same type?

I'm not after detailed plans, or even a whole circuit - the "icing on the cake" bits like TX/RX sensing, the power supply system, the lowpass filter on the output stage, etc, etc, are not needed.

What I am after is the methods used to connect 4 output devices of the *same* type (i.e. 4 x mrf454, or even 4 x 2SC1969's) together to achieve approx twice the output power that a pair of the same devices would achieve. I presume the "secret" is in the transformers used in the driver and output stages....

The amp is intended for use in the 40 and 20 metre ham bands only, to simplify the LPF stage more than anything else - SSB/CW only.

Any info would be very appriciated.

Reply here, or preferably email to: lbc@senet.com.au

Regards,
Chris.

Well, just drop by the QRP list at lehigh.edu sometime. The group
is highly devoted to homebrewing, and is growing every day. In
addition, just look at the number of kit companies and construction-
oriented clubs that have popped up in the past few years. Granted, QRP
is a niche market, but it is still a *growing* niche market, and
doesn't show any signs of slacking off.

>Any ideas? Would appreciate e-mail and others may want posting. Thanks.

Telephone modems faster than 2400 baud go through a training and
negotiation phase at connection startup. This can't be bypassed by
an AT command. However you can use what is called a "short haul"
modem. These are designed to operate over leased lines and expect
a consistent EQ, hence they don't train and negotiate. Immac carries
several brands of these short haul modems. 9600 baud units are common,
and fairly cheap, faster units are available. They expect a 4-wire
interface, thus they should work on a good voice grade radio circuit.
(They can't deal with multipath, however.)

It *is* possible to force a Group 3 FAX modem to work on the radio
channel. There is a test mode for some of these which allows them to
go on-line without training. This can give you 9600 baud data. Some
amateurs in Japan experimented with this for a while. It's not an
AT command, however, you have to actually strap pins on the modem
chip to put it in test mode.

For robust operation on a radio circuit, you really need a radio
modem. And for speeds over 2400 baud, you really need a data radio
and not a voice radio kludge. Not only does this work better, it's
usually cheaper too.

Last week (10/1 - 10/4) I put a plea for help for info on Cubic Electronics in Ocean Side, Ca. Some very nice gentleman gave me the info I needed. I have since had a complete system crash and lost ALL my messages...in fact I lost 2 hard drives with everything on them. The only thing I remember about the message was that his address started with something like "HONT"..his name was Loenk (?), The important thing was, he gave me the name of a guy that had worked for Cubic. He said the guy still repaired Cubic radios for a fair price. H ealso said the guy had a fax on during the day but in the evening it was off line. He gave me the telephone number and all the info I needed. I can't remember which newsgroup it was in. If he will PLEASE contact me again I would appreciate it very much. I need the same info again.

I am posting this to all the ham and radio newsgroups to find this good samaritan again. I sent him a thank you message, but of course that is also gone now so I can't get the address from there.

It sounds like the "unusual device" is a bias stabilization and tracking device ... CTC used to make one called a BYISTOR ... it's coupled tightly to the heatsink so it tracks the junctions of the RF devices to help prevent thermal runaway. The 200 Ohm trimmer is clearly the means of adjusting the "idle bias" of the class AB stages for the desired quiescent current and linearity.

>> Roger,WF4N

Depends on what you mean by the "technical aspects". I tend to use
my homebrewing to experiment in areas that might be outside of my
current knowledge base, such as DDS, DSP, software control, etc.,
instead of just soldering up another version of a QRP rig.
There is a ton of interesting stuff that can be done fairly easily
and cheaply in the DSP area for example that can really improve
your homebrew designs, as well as helping you to learn a valuable
new technology. There is currently much discussion about software
radios, and there is quite a lot that the amateur homebrewer can
do in this area, it's just that the tools and techniques are going
to be different. Instead of a soldering iron, get a C compiler for
your PC. Instead of another breadboard, invest in a DSP starter kit.
The game is basically the same as it was before, but to play effectively
you may need to change your skill set. In the end though, it really
is the same to homebrew in software as it was in transistors and tubes,
as you are doing it YOURSELF.

For more on how homebrewers can get started in DSP, see the 7/96 issue
of QEX...

I'm trying to take a 90's approach. Just got in my box of minicircuits
VCOs, and made a logarithmic amp from the National Semiconductor data
sheet for one of their opamps... Together with info gleaned from KK7B's
direct conversion receiver, a spectrum analyzer is my next project.

With a VCO and a mixer, a nice 0-50 MHz VFO should take up the size of a
pack of cigarettes, and is also on the project list.

Greetings All:

I would like to obtain an off-the-shelf crystal filter for a project I am working on. I have checked Digi-Key and Allied and neither carry a line of good quality crystal filters.

For my application I may be able to utilize a 10.7 MHz 12 KHz BW NBFM 8 pole filter. A list of available filters to browse through would be nice.

Does anyone have any suggestions for known sources of crystal filters???

Thanks in advance for any help!

I recently evaluated a section of orange 1/2 inch ethernet coax. It's
very good, loss characteristics quite close to foam RG-8 with a measured
attenuation of 4 dB per 100 ft at 450 MHz. This section was triple shielded
with a measured VF of .77.

1812. Is equipment building and repair a lost art? NO!

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-11 00:00:00 UTC
From: lhalliday@creo.COM
Message-ID: <9609118450.AA845057728@mail.creo.com>
Source record: 101800

I'm baffled at why this is even a subject for discussion - homebrewing is easier than it ever has been, the parts are better than they have ever been, and homebrewers can make equipment of unprecedented sophistication and performance easier than ever before.

Parts? I've never had any difficulty getting any parts I want. Sometimes you have to make a few phone calls. Sometimes you have to get them from overseas. The fact that you can't always get things locally is irrelevant: in this age of direct overseas dialling and credit cards, "local" is meaningless. For the really neat stuff sometimes the only way to get onesies and twosies is as samples. So what?

PC boards and construction techniques in general are a red herring. My approach these days is that one-offs are best done on unetched ugly boards, which are quick to make (perfect for let's-try-it-and-see experiments), work extremely well up to at least VHF, and can be real works of art. I long ago decided that (except for reproducing stuff from books and magazines), if I etch an original board, it will be surface mount. And please don't start whining about *that* - SMD is available, cheap, dead simple, idiot-proof and very nearly indestructible. I laid out my first SMD PC board with a straight edge, scotch tape and a sharp knife...

The dismal level of technological interest, knowledge and expertise is indeed a problem. The way to address it is not to grumble about the new tests or new hams, but to acknowledge that now, with it being so easy to get on the air, the role of Elmers is more critical than ever before. Your licence is your licence to *learn*. Just do it.

I'd like to propose some self-censorship on this subject. Can you imagine the effect such discussions have on young or would-be hams? "Modern technology's crap! The Good Old Days are over! Face it, loser: you missed all the fun!" Ugh. The *real* fun is yet to be, and if some hams wish to opt out of technology and live in the past, please at least have the common decency to keep your mouths shut and stay out of the way of those of us who still understand what "technical investigations and self-training" means.

10base-T is unshielded twisted pair.
10base2 is thinnet (RG-58 or similar w/BNC)
10base5 is thick ethernet (kinda like RG-8 w/ N-type terminations and 'taps'
that are installed through the side of the cable)

No, that would be 10-BASE-2. He has the heavy duty thick stuff that
they bolt the transeivers to.

I don't have my catalogs hadny, but I have heard of hams using this
stuff with some success. I don't recall any numbers on loss but I think
the stuff was around 50 Ohms.

He's right. If you really need to get precisely 12.0 Volts you will need a switching power supply. Then you can set it up to run from 8 to 16 V or so. Protect the input; you can protect from severe transients with a fuse then a 18 or 20 V beefy Zener, or just LC it with a big C.

Do you really need 12.0 Volts? or just well filtered 13.6?

I think the Amateur Community is not as " tuned into " electronics as it once was. With the actual queations and answers presented there is no need to learn Ohms or Kirchoffs law How many can calculate the gain to a common emmiter amplifier circuit. You do not learn that by reading a Q & A Manual.
I used the ARRL License manuals in the early 1970s. It was basically a sylibus (sp) of what one needed to know to pass the exam. Then you " hit the books " for the answers. Now you just memorize the answers to the questions. Sure some knowledge has to soak in, but the majority appears to be forgotton once " you passed " is heard . I happen to be in the business and the kinds of questions I receive have really changed over the 7 years I've been involved. Now I speand most of my time merely reading the manual verbatium to the caller who appears to be willing to pay long distance charges to be read to. Not complaining, the customer needs and abilities have changed over the years.
I have chatted with EE degreed Extra class license holders who could not cut a dipole antenna which I found amazing but true none the less.
I do agree the need for club projects, how about showing some club members how to photo etch a circuit board, or what positive feedback really does, build an antenna tuner or SWR meter Building is great fun. It's up to the builders of the community to give a hand and show the new comers what they are missing

Gary

The most common problem with IC22S is the stainless steel
feedthrus on the PLL board. The second most common problem
is failure of the divide-by-N chip. Replace all the steel
feedthrus with copper wires soldering both sides since
the PCB is not plated-thru holes. Unfortunately, the
divide-by-N chip is out of production. If you can't fix
it, I would be interested in acquiring it from you.

*** Please reply through Email as well - thanks ***

Yesterday I bought a Sommerkamp FRG-7 at an auction. The Sommerkamp FRG-7 is AFAIK identical to the Yaesu FRG-7, and a colleague of mine told me that if you peel off the Sommerkamp label, there's a Yaesu label right underneath, so that should be no problem. :-)

My new FRG-7 looked fine, but when I tried it at home I discovered that the PLL won't lock. As far as I know, the FRG-7 has a 1 MHz XO, and a tuning knob that controls a VFO, which is then phase-locked with the 1 MHz XO signal, to get multiples of 1 MHz (1, 2, 3 ... 29 MHz).

The red 'Lock' LED on my FRG-7 is always on. The PLL won't lock, I don't get a stable multiple of 1 MHz but instead the 'multiple MHz' VFO acts as a free-running oscillator.

I don't have much experience with the FRG-7, but years ago we had one (the Yaesu version) at the Hydromechanics Lab at Delft Polytechnical University, and I remember that the red 'Lock' led used to go off when the PLL was locked. Do I remember this correctly? If not, what is the correct procedure to tune a FRG-7? Does the PLL also lock (I think it should) if no antenna (or only a short piece of wire) is connected?

What's the idea with the small button at the right side of the tuning scale (marked 'Tune' and 'Set' if I remember correctly, I don't have the receiver here at the office right now)?

I am especially looking for (copies of) the owners manual and service manual (esp. the circuit diagram) of the FRG-7. Preferably from someone living in the Netherlands. :-)

*** Please reply through Email as well - I can't read the newsgroups often. ***
Any reply greatly appreciated!!

>My first guess would be that it's a poorly formed label for a NEC chip.

>Only way to find out is to get the manual. Something that Radio Shack
>is really pretty good at

The radio is made my Uniden. There are 2 versions of the chassis, one
a "compact", the other a larger "full size" board - but the circuits
are basically indentical electrically.

The 2824 is the PLL synth chip, ROM encoded with only the 40
FCC channels, corrosponding to a count of 91 up to 135.
A 2 output is also there, which is tripled and mixed with the
VCO to yield the 0.91 Mhz to 1.35Mhz signal used to lock
the PLL loop.

There are two ham-mod methods. First one is to add an
external (from an added crystal osc) signal to the tripler's
output... but this has three problems. One, you'll be limited
to 40 channels, gaps/skips/etc and all - and two, as the
clarifier works on the 10.24 ref xtal, the clarifier range will
be *severely* reduced. Three - the USB/LSB offset works
the same way as the clarifier, so you'll need a slightly
different crystal for LSB if you intend to use it as well
as the usual USB.

Second method - add another PLL. The Upd858 will
cover at least the bottom part of 10m before the
counters run out of steam, and a motorola MC145151
will allow full 5Khz step coverage from 26 to 32 Mhz.
The clarifier and lsb/usb offsets will function correctly.

Note that the original PLL chip is left in, as it's tripler
and downmizer functions are retained - the second PLL
is added and runs alongside the original one.

Email me (lbc@senet.com.au) if you need more info.

Good luck!

Regards,
Chris.

I stand corrected. However, now this means that I have to actually
go to the "trouble" of learning, all over again, just like when I was
a kid. H-m-m...
Thanks for the kick start...

Years ago I built a 10GHz doppler speed measuring device. (Radar
means "direction and ranging", so I am hesitant to call it Radar.)
It used a 2K25 reflex klystron and a magic "T" to a small horn
antenna. The output fed an audio amp and a home-brew audio frequency
meter calibrated in MPH. Right now I have some similar home
brew equipment, with dual horns, but I don't have any plans to
put it back on the air.

1838. Need schematic for 6L6 or 6V6 homebrew transmitter

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-12 00:00:00 UTC
From: gekko@nwlink.com
Message-ID: <53p0d0$kps@texas.nwlink.com>
Source record: 101820

Maybe someone out there can help me out. I once built a 6L6 transmitter (single tube) for 40 meters and had a ball with it. I'd like to do it again, but I can't put my hands on the schematic. Since I have a number of 6L6 and 6V6 tubes, I want to use one of those (realizing, of course, there is a power difference between the two). I believe the one I built even had a PI tank output for a 50 ohm antenna. Any low power (5 to 25 watts) rig for 40meters or higher that can tune a 50 ohm load would be perfect. I have alot of my old novice Xtals plus a VFO to boot.

If you have an old QST, 73, or CQ article with such a project, maybe I could get you to fax it to me?? Or maybe scan it and email it if possible??

Please email if you can help.

Thanks

Gordon

Intel 80C31 MicroControllers equals for sell:

These are the Signetics SC87C51CCN40 part number. They are one time programmable and have been programmed. However, these become just like the 80C31 once pin 31 is tied to ground. They are the 40 pin DIPS.

They will operate at 12 MHz.

If interested, I would like $2.50 each plus $1.50 shipping for one to three. Four or more, I will ship.

Contact S87C51@aol.com for details.

Thanks
KJ4UO

It's their Orange County CA dial-up that's messed up, that's all.
Anyway, I just posted in alt.binaries.pictures.misc & 12hr & clocks
two image files, one a picture of the modified AA5 radio using the
sub-mini tubes, and the other image file a schematic diagram.
This radio was missing its back, and its antenna, so I had to
make a new loop antenna from ribbon cable.

This would file under: "What If", what if sub-mini tubes were to be
the next generation of consumer tubes (and what if transistors not
been developed). Also assumes that the manufacturing costs of
sub-mini's became reasonable (would happen when you make billions
of anything, you find ways of making it low cost). As it was, only
the military could afford sub-mini's.

>diverged. The direct relationship of component to function was hidden
>and homebrewers simply couldn't fabricate PC boards *easily*.
>Still can't, but at least design and layout is a lot easier now.

I don't know about that. PC board fabrication is pretty easy, at
least if you don't want multilayer boards, which you usually don't
for RF projects. And the rise of SMD components has eliminated
the need for lots of precisely drilled holes too. SMD is a godsend
for the homebrewer. It is much easier than working with leaded
parts.

CAD has made layout lots easier, but tape still works, as does
simply drawing the circuit on the blank board with a permanent
marker. So cost and complexity of layout tooling really isn't
a concern for most projects.

I usually print to transparencies with my laser printer and
photographically transfer the circuit to the board, but I've
also used a plotter directly onto the board (you need a plotter
which will run very slowly to lay down enough ink, and that's
good because it usually means you want an older cheaper plotter).

I think the ideal setup would be a photoplotter. I've thought
about taking one of my old junk plotters and replacing the
pen with a laser diode. I'd use the pen down and pen up commands
to turn the laser on and off. That way I could plot the circuit
directly to photosensitive board stock. My only concern is that
the red light won't work with the common photoresists. Perhaps
there are resists suitable for this. Has anyone tried this?

Etching is an easily learned skill, and the equipment needed is
very modest. I've done it with just a glass bowl in the sink,
though a cheap aquarium tank and bubbler can lead to nicer boards,
as can good temperature control of the solution. All you need can
be found at the local fishy shop, or at a garage sale.

The one real difference is that you need to be pretty sure of the wiring of your circuit before you commit it to copper. While you can hack a board later to make revisions, it is often ugly and can introduce strays you don't want. This is where the circuit simulation tools can come in handy.

I also do a bit of dead bug style building. I use unetched board as the substrate and solder or hot glue components to it with their little legs sticking up in the air. I use solderable wirewrap wire to make the connections, spinning it on the pins then soldering it later when all the connections are made. That works pretty good.

For most low impedance RF work, if I need a tiepoint other than a component pin, I'll just solder a 10M resistor to the board and stand it up so I can use the other end as a tiepoint. Of course direct access to the groundplane is everywhere on the unetched board. I don't do it, but I've seen others glue down small pieces of circuit board to form isolated pads.

IMHO there are many good ways to build using copperclad board. I like it much better than the old point to point style wiring.

Gary

One watt ERP! Man, wish we could do high power stuff like that!
We're limited to one watt *input*, and given the limits on antennas,
the ERP is better expressed in microwatts, or at best as a few
milliwatts. An extra 30 db of signal would make things lots
easier.

Amateur Radio is the place for ALL forms of radio activity, nostalgic or leading edge (well, relatively speaking anyway). As a fraternity, we should be encouraging this spread of activity.

I started in electronics when germanium transistors were hot property (literally from thermal run-away) and valves were bread and butter. I wouldn't consider using valves in a project, but I still like to see the craftmanship that was evident with the loomed wiring, component leads bent just so around the terminal posts, etc. The vintage cars of radio.

Mark.

I recently obtained some Montrose 5713 50 ohm ethernet cable and am
trying to get mnfr's. specs. but I've found the following by
measurement.
1) An open 41 ft. length gives approx. SWR of 9 to 1 at 144 Mhz. This
calculates to a loss of about 2.3 dB/100 ft.
2) The velocity factor is close to 80% and the dielectric is foamed,
because the temperature rating is 125 C I believe that the dielectric
is foamed teflon.
3)The cable is well shielded with both foil and braid.
As best I can tell this cable should be quite useful at 144 MHz. I
intend to use it for baluns for some 2M yagis.
Would appreciate receiving manufacturer's specs.

John KB9MIE.

Hams with transmitter building experience, please
consider helping victims of civilian electromagnetic
weapons testing. We want to build a demonstration
device to show public officials that this type of
weapon exists right now, and is not some sort of
futuristic "pie in the sky".

We have signal specifications. To view those specs
and for further information, please visit:

http://www.netaccess.on.ca/~raven1

Thanks for taking time to read this.

I have had some success placing the Gunn in the emitter of an NPN emitter follower circuit. The base is driven by a video speed opamp (Elantec and National Semi make several now). The feedback for the opamp is from the input to the opamp to the output of the emitter follower. The video waveform and DC Bias for the Gunn are applied to the opamp input in a summing configuration.

The biggest trick here is to keep the connections to the Gunn as short as possible. You also need to make a trade off between good bypassing of the Gunn (to prevent secondary oscillation) and the ability to modulate at video rates.

Sorry I don't have an actual schematic to post. The last circuit I made went directly from my head to the board. Hopefully that will give you some ideas.

I need help. I need to build a battery charger for a radio I bought at a hamfest a few weeks ago. It has a 7.6v nicad battery with two negative contacts one positive contact and one other contact. I recently built a 5v regulated power supply and was wondering if I could use that as a charger and if I can, which contacts do I connect to?

Thanks,
-Chuck

>>available, cheap, dead simple, idiot-proof and very nearly
>>indestructible. I laid out my first SMD PC board with a straight edge,
>>scotch tape and a sharp knife...
>>

Agreed, but they WILL whine about it ... it's NEW ... they don't
understand it, don't WANT to bother learning about it, and are deathly
afraid that the trend towards modernization will continue ... notice I
said "are deathly afraid that the trend ... will continue" they're so
far out of touch with today's technological reality that they haven't
yet accepted the fact that progress "is a done deal" and that there's
nothing that can stop it ...

>>The dismal level of technological interest, knowledge and expertise is
>>indeed a problem. The way to address it is not to grumble about the
>>new tests or new hams, but to acknowledge that now, with it being so
>>easy to get on the air, the role of Elmers is more critical than ever
>>before. Your licence is your licence to *learn*. Just do it.
>>

Too many don't WANT to learn ... to them "It's JUST a hobby! <whine>"
All they want to do is work DX, collect wallpaper and bitch and whine
and try to keep out newcomers who might actually do something of benefit
to ham radio ... after all, "can't have those damned no-coders getting
in here and actually doing good things ... would make us brass-pounding

olde fartz look bad (worse)"

>>I'd like to propose some self-censorship on this subject. Can you
>>imagine the effect such discussions have on young or would-be hams?
>>"Modern technology's crap! The Good Old Days are over! Face it, loser:
>>you missed all the fun!"

Those are exactly the effects they want ... they want to keep out the newcomers ... they can't stand the fact that some sharp young technowizkid with a talent for design and an eye for progress can do more good for ham radio in his first year than they did in the past 25 years of chasing DX on the lower part of 20m and bitching and whining about newcomers ...

>Ugh. The *real* fun is yet to be, and if some
>>hams wish to opt out of technology and live in the past, please at
>>least have the common decency to keep your mouths shut and stay out of
>>the way of those of us who still understand what "technical
>>investigations and self-training" means.
>>

Don't count on that Laura ... you're destined to get flamed for what you wrote ... it's "heresy of the highest order" ... anyone who advocates progress, says that ham radio is more than a hobby, and that CW is not better than sex is a heretic in the eyes of the ARRL/Morseist Religious Order of Olde Fartz.

But welcome to "the rabble" ... we can use all the vocal support we can muster for the coming battle to get the rules changed to eliminate the code test and modernize rules regarding modulation, coding, occupied bandwidth, etc. Plus, we need more YLs <grin>

I like to transmit a video-signal (fbas/ntsc or monocrome) from a radio controlled airplane with an amplified tv-modulator. My problem is to filter and amplify the signal to get a acceptable transmission of 500m or more. My power source is 12V and the modulator frequency is channel 2 or 3 (somewhere between 50-100 MHz). How do i connect what kind of transistor to what kind of antenna and how do i filter? I do not have much experience with hf circuits. My maximum range of a good signal was 10m.

>. . .

I'd like to add my strong agreement to this. Circuit boards are super if you want to make several copies of something. But for a single unit, they're totally unnecessary. It's frequently much harder to get good performance of RF circuits on a circuit board than it is on an "ugly" style ground plane. Being able to build point-to-point in three dimensions enables many connections to be shorter.

Years ago I was visited by a ham who had been living in Tonga, in the South Pacific. He had been trying to get material together to build PC boards so the local hams could build rigs. He'd experimented with using dilute battery acid for echtant, and made other efforts to make do with what he had available, but hadn't been very successful. He visited my place and used some of my homebrew "ugly" construction rigs, then we went to Wes Hayward's (W7ZOI) place and he saw and used some of Wes's rigs. He was amazed that such ugly rigs could work so well, and told us so. He had been sure, after reading all the articles in popular magazines, that PC boards were necessary. Armed with this new information, he returned to Tonga. I talked with him on the air a short time later, using a new rig he had built, "ugly" style. "Looks like hell," he said, "but works terrifically. And we're on the air."

The term "ugly construction" comes from an article by Hayward (KA7EXM) and Hayward (W7ZOI) in August 1981 _QST_ titled "The 'Ugly Weekender'". For more information about this technique, Look in the index of _The ARRL Handbook_ under "Ugly construction".

I think the constant emphasis on PC board construction has done as much to supppress homebrewing as any other factor.

Im a bit new at this but after getting my W1FB Universal DC RX going
I began to wonder if I couldn't add a selector switch and switch in
different torroids and caps for two or more bands.

I realize this could cause a bit more instability but if leads are kept
short etc. is this a resonable idea or is it not worth the effort?

Roy:
Its C.C.I. and they advertise in QST. Just saw their ad a
couple days ago. When you get a hold of them, ASK them if the
Motorola instructions/data come with the kit. I am interested too,
and in fact have their catalog here somewhere, but I moved houses
and I can't find anything yet!

Please be advised this is a parts kit. IE, blank heat sink
extrusion that you drill, etc. Seems like there has to be a limit on
how "pre built" the kit is or runs afoul of FCC rules on amps. Its
just a collection of parts, but I understand the PC board comes ready
to go, so it is not hard at all. But ASK. My last contact with them
was about 4 years ago and anything can have happened in the meantime.

Let me know what you find out both questions. Note the
message on my signature line about e-mail reply before you use the

1867. QRP homebrew list

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-14 00:00:00 UTC
From: "Bradley S. Mitchell" <bmitchel@kodak.com>
Message-ID: <32625588.6870@kodak.com>
Source record: 101750

Hi everybody,

I have been on the QRP-L for a long time, and have seen
the list change considerably since it started.

Because it is becomming a list more of people building
kits and Chasing foxes, I proposed that a new QRP-HB homebrew list be created.

Many people e-mailed me directly, and said, good idea..Many
posting to the list directly said, No Way.

Now, my question is is there enough interest out out there to support
a QRP-HB (Homebrew) list or not?

By some people on the list, I was told to come here and post
(rec.radio.amateur.homebrew).

With the current thread that is going on here, it seems that
Homebrewing in general is at risk.

What do you all think?

I agree, and would support a HB list, the problem with the QRP-L in my opinion isn't so much QRP operation vs Homebrew but it seems to be taking on all kinds of other junk. Contests that are not QRP endless commentary that just offers another opinion.(yea I know, like I'm doing here) It's getting to big for me to wade through each day.

1870. The bandwidth of the technologically impressed & homebrewing &c

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-14 00:00:00 UTC
From: nyoung@nova.wright.edu
Message-ID: <1996Oct14.121122@nova.wright.edu>
Source record: 101753

And furthermore, he said with the air of a pontificating putz, it ain't so much that technology is zipping onward with exponential increases in speed. It's the bandwidth of the technology itself.

One of the discussers here had mentioned DSP &c as a place due for more research, more trial and education. I agree. It's like saying that television must forever more remain NTSC (or PAL or SECAM, if you live in those worlds) and that never should digital concepts be passed down to the television viewers or market. To do so would ignore the changes in the building of TV images over the past 20 years or so. As in: I remember back around 1972 reading in the now-defunct _Ham Radio Magazine_ about some guy who was messing with the then neonatal forms of CCD/pixel-oriented image building. There was a picture of his callsign plootsched out into a 1-inch square of very tiny boxes. I looked at that and said that TTY (as we knew it then) was headed for the dumpster. I was right. Now we have OCR systems that do away with "cutting tapes" for RTTY; we have laser printers and DMPs that do away with TTY "stunt boxes"; we have digital modes that add almost uncontrollables levels of encryption & security (spread spectrum being only one of 'em), all far beyond the wildest dreams of any RM2s and RM3s that I knew back then.

In fact, those ol' pixels now allow me to put a monstrous image of Hulk Hogan or Macho Man Randy Savage on my living room wall so as to not miss one glob of flying spit as either of 'em hits the turnbuckle.

THe change is there, as it always has been. And yet, I personally derive a certain arcane pleasure out of recreating -- especially for my eight-year-old ('cause he likes it) -- one tubers and crystal sets... if only because they are such great teachers of the fundamentals at the core of this broad spectrum of technological change. ANd it makes me feel good too, knowing that as much as I have gotten older, I can still figure out which tube pin gets the 6.3 VAC and which gets the 110 VDC. That stuff -- the details -- are terribly important. I have a ARC-5 receiver with blown filaments to prove it.

So before anyone gets sidetracked by my references to tubes and the popularly hot-ticket CK722 (remember them?), maybe I should make my personal position clear:

To bring Freud into the set-up, sometimes a cigar is just a cigar. Food is food. I like grits with my over-easy eggs. Other's hate the white stuff and want only well-greased, fried in lard, thinly sliced hashbrown potatoes. But either way it's "plug 'em up and die;" we still end up eating breakfast. So I dig old tube radios 'cause they're

my last ditch nostalgia trip. That doesn't mean that I wouldn't take a multi-mode 440 MHz transceiver. Fact is, I'd love to have in one box 30 MHz of spectrum to match the 30 MHz of HF spectrum that I have in my antiquated TR7. That and a new Barco 3000 LC so Hulk Hogan could be even more real as he flops head first and nearly broken onto the mat. After all, that guy back in '72 had a pretty good idea. If only I could get myself fired up about SSTV... as if drooling after the latest RisoGraph duplicator ain't enough to make me reconsider the 1890s-vintage type collection what already clutters up the garage. And, now that I think of it, that's a spectrum too: print media of my father's day, print media of my son's youth, electrons & all.

Anybody for BPSK on 1.75 km? (But first you have to explain what BPSK is... nice and slow... so I can copy down the dits and dahs.)

I'm in violent agreement with Roy on this. I think that magazines tend
to want PCBs to be available so that casual builders can order a
PCB, stuff it and have a working thingy. That's nice for "canned"
projects, but experimentation ends up being stifled. I've been
building ugly things for some time, and it really is great. I'm
not stuck using someone else's design - I can (and do) frequently
cook up my own.

The 2m/220 transverter project in the '94 (and maybe later)
ARRL Handbooks is a great example of what ugly can be.

Thanks to all who replied for help regarding a shorted out SCSI
Hard drive (two of them). I found the problem with one by current
limiting a +5volt supply and checking around for a HEAT SOURCE
(high tech -huh?). Turns out it was VERY SMALL 22uf/33volt surface
mount tantalum cap. I believe the second drive has the same component
failure, but I am still looking.

Thanks again for the help.

1878. Power Supply as Battery Charger

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-14 00:00:00 UTC
From: mvi@ix.netcom.com
Message-ID: <3262C584.7627@ix.netcom.com>
Source record: 101761

I tried to use my 13.8v / 3 amp regulated power supply to charge a 12v / 7 amp/hr nicad.

I let the battery charge for about three hours. At this point, the current being drawn by the battery had dropped from about 2.4 amps to about 1.45amps and the voltage at the battery, without load, rose to about 13.1v.

The following morning, I re-connected the supply to the battery and saw a small spark when attaching the positive alligator clip to the battery (with the supply off, of course).

At that point the supply ceased to work. Further investigation found two open transistors in the supply.

Questions:

How does a battery charger differ from a power supply?

Is there a way to modify the supply to be able to use it as a charger?

Any help would be greatly appreciated.

Thanks,

John, KB2YJH

About 2 years ago, I built a 6GHz synthesizer using "Ugly" construction
techniques. In this case, it was a combination of dead bug, holly board
and zero lead length coaxial techniques with SMT components. It worked
great. Even though it was done for my employer, it could have been easily
a ham homebrew project. The only special tools were a fine tip iron and
an articulated magnified lamp.

AFAIK, sub-mini's are fairly similar to regular tubes, just like the mini
7 and 9 pin-ners are similar to octal tubes. Though not identical.
I have done things like substitute a sub-mini filament 5678 for a 1u4 in
a tube portable AM radio with no extra mods needed. And the before mentioned
AM "AA5" tube radio, which needed only small mods (change resistor values,
and such). The 6111 is a medium mu twin triode, similar to the 12A_7 series,
heater voltage is different! I don't know of a web site with info, maybe
I could post some info on ones AES sells. These tubes are a bit pricey
though. The 6111's they had a sale for $1 or was it $1.50? Usually around
$12. I picked up from an old book dealer a GE tube manual, which lists sub
mini's.

Brad:

Your posting has had me waxing philosophical. Stuff like humans need to communicate, and then when given the method or opportunity, have nothing to say.

As an old CW op (1952) I recall many 'identical' ?conversations?:

XMTR IS . . .
RCVR IS . . .
RST IS . . .
GOTTA GO

I guess my point is that I found it so exciting to fire up that 6L6, press the key and hear my call letters coming back. Beyond that it was just QRP, DX or as you say Fox hunts. The medium was the message.

I am interested in Homebrew. Homebrew anything. It's something that I can provide some helpful information on at times. Kits are not homebrew. My own take on QRP is that it's small, cheap, portable and doable. I've had this fantasy of camping on some mountain ridge, with my antenna strung in the alpine firs, snug in my sleeping bag, tapping away to someone sitting in their shack in town.

Is there more than that?

When did Digi-Key start selling Motorola parts? I've found that Mouser and Digi-Key are not good source for things like Motorola PLLs (like the MC145157, MC145170, MC14519x, etc.). They don't sell Motorola, and they don't stock too many 'exotic' chips from the vendors they do sell.

I've bought Motorola PLLs from Hamilton Halmark, Wyle and (I think) Newark. You've got to deal with a decent distributor for these parts, and they're usually easy to get once you find the right source. The last time I shopped at Hamilton Halmark, the minimum order was $50, which I easily made. I stocked up on MC145170s and J310s.

However, the original requestor is not in the USA. I'd suggest contacting a local Motorola sales office (look in a databook) for the names of local distributors. It has always worked for me.

-looking for plans for a small transmitter to be used in Fox Hunts.
-
-Something in the very low power range (10 mw would be plenty!) and
-maybe even with a voice chip although a code output would work as
-well.

I'd start with an old HT (Icom 2AT or similar) and either build a keyer from an EPROM, counter, and 555s (see the handbook for the circuit) or use a timer to trip a voice chip like the Radio Shack one or one from a greeting card. For a real nice setup, look at http://home.navisoft.com/agrelo/ae.htm Joe sells some very nice mini transmitters and DVKs, as well as a very nifty doppler DF'er.

I'd stay away from the Ramsey FM-6 transmitter; if you do build it, MAKE SURE YOU ADD AN EXTERNAL FILTER and put it on a spectrum analyser. It has *no* output filtering and puts out spurs and harmonics all over the place. Not sure about their "Sly Fox" transmitter, but I'd put that on the analyzer too, given Ramsey's reputation...

Hello, Folks:

My radio club (The Eastern Ozarks Amateur Radio Club) and I are looking for plans for a small transmitter to be used in Fox Hunts.

Something in the very low power range (10 mw would be plenty!) and maybe even with a voice chip although a code output would work as well.

It must be:
2 meters
FM detectable
Battery powered (8+ hour battery life if possible)
Very small

We don't want to re-invent the wheel if there are already plans available.

Thanks!

Take Care & 73

1888. Re: Using Ku TWT for X-band

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-14 00:00:00 UTC
From: rex_allers@3mail.3com.com
Message-ID: <53u1s4$8gv@news.nad.3com.com>
Source record: 101771

A week or two back someone asked about using a 12-18 GHz TWT for 10 GHz... sorry, I lost the original post. Hope you are still around.

I haven't done this myself, but it has been done by several hams for X-band operation. It will require that the TWT not have waveguide feeds with a cutoff above the desired band. If it has waveguide that is broad enough for X-band, or SMA or N, it should be do-able. You may need to lower the high voltage which will lower the operating frequency, and some magnets added around the tube may help peak the output and lower helix current.

Jim Vogler, WA7CJO, did two excellent presentations with lots of TWT tips for microwave hams -- "Optimizing TWT Power for Narrow Band CW/SSB Operation" and "10 GHz Moonbounce". They are both contained in one of the Proceedings books available from the ARRL. The one for these articles is "38th West Coast VHF/UHF Conference -- 1993". According to the ARRL list it is still available for $12.

You can reach ARRL on the web at www.arrl.org or by email to hq@arrl.org. The various ARRL proceedings are an extremely valuable source for microwave hams.

Store is renamed and moved to a stripmall a little ways down from where you
used to turn for the superstore. Called Electronic Planet. They also have one
on 101-A West from DW Hwy. (Rt.3) in Nashua, NH.

>>>They'll refund your money if you buy something from them and find that it
>>>doesn't work when you get it home.

Assuming you didn't buy it in "as-is" condition.....

>>They used to be in Woburn but I couldn't find them about a month ago.
>>I believe that they have moved it all to New Hampshire (darn) . Is Eli

They started in NH and expanded to MA.
Known as ESS/Electronic Planet/Electronic Surplus Services in Manchester,NH.
Granite St exit in off 293N. Right at lights,
right at next lights, right again into parking lot.

> That's a shame. I wanted to buy more stuff from them for a 'mad scientist'-
> style art installation. They had a ton of omnious looking meters/gauges/etc.

You won't find any of that at the Woburn and Nashua stores. They are trying to
be a retail outlet at these stores and are selling a lot of new low quality
china-made computer peripheral stuff, old, used, computers and a small
selection of some new, imported electronic parts (mostly GC switches). Your
best bet for older surplus parts and a bigger selection is to go to the
Manchester NH store.....

I keep my parts on their tape rolls until I'm ready to install them.
I write the value on the tape when I hang it on the bench dispenser.
I thought everyone used a binocular microscope on a floating arm
when working with modern circuits. :-) A jeweler's loupe works too
in the field. I haven't been able to work bare eyed, even with 1/2-watt
resistors, for years.

> 2. With a leaded part you just stick the leads through the

Well, first you have to *drill* all those holes, and precisely too.
That's a *very* major pain in the ass. I've got a CNC drill, but it
takes so long to set up I can be finished building a SMD board by
the time I have a thru-hole board drilled. If you're buying your
circuit boards, you aren't homebrewing, you're doing kit assembly.

> a must, and the proper kind are hard to find.
>
> And a good soldering iron is essential (Metcal stations are
> great).

Your SMD technique is *horrible*. Forget soldering irons, use a static hot air source. I use the little pocket Weller Pyropen Jr for most of my work (no cord). The first step is to use a wooden toothpick to put a tiny dab of solder paste on each pad. Set the part roughly in place with a pair of fine sharp tweezers (the cheap Pakistani kind are fine), get the tweezers out of the way, then hit the part with the hot air source. When the solder paste melts, only takes a second, it'll pull the part into perfect alignment by surface tension. Back off with the hot air source and let cool. Perfect joints every time.

This technique solders all pads at once. Weller has a number of hot air shrouds for the Pyropen Jr, use the one shaped to fit the particular part you're working with to avoid heating things you don't want to heat. Most work can be done with 3 basic shrouds. I also sometimes make my own shrouds for particular situations. As the board density increases, you may choose instead to use a bit of modeling clay to form a heat dam to keep the hot air source from reflowing the solder on another part. I keep a little wad of it in my rework kit.

> 3. With a through-hole part it's much easier to see if it was
> correctly soldered. I've had more problems over the
> years with SMD parts whose leads are not all soldered to
> pads than I have ever had with through-hole parts.

If you'll throw away that iron and switch to hot air you won't have those bad joint problems, the parts will always be perfectly aligned, and will lay flat against the board (unless you used too much solder paste, remember just a *tiny* dab on each pad).

For rework, I've finally found a good use for solderwick. For years I've spurned that stuff in favor of a vacuum desoldering tool, but it is great for cleaning up SMD pads in preparation for installing a replacement part. To save on consumption of that expensive stuff, keep some solder flux handy. Just heat the end of the solderwick a bit with the hot air tool and then dip the wick in the flux. It's almost like new again.

It is easiest to remove SMD parts if the board is loose on the bench. The way I usually do it is to form a dam with the modeling clay to protect surrounding parts, heat the part to be removed with the hot air (only takes a second), and then rap the board sharply against the bench. Part falls right off. If the part was glued down during assembly (boo hiss), you may have to use those sharp tweezers to pry it off instead. This takes some dexterity because SMD parts cool *fast*, so you have to work fast or you'll wind up lifting a trace that's cooled while you're getting the tweezers in place.

SMD has very little thermal mass, so you always have to work fast, when installing or removing parts. It only takes a second. But this also means you almost never damage a part. You can reuse good parts removed from boards as easily as you can use brand new parts. I'll admit that keeping track of the little buggers once they're loose

is a bit of a challenge. I keep labeled ice cube trays handy to pitch
the little guys into before I forget what they are or lose them in
the bench clutter.

1896. Re: Help re simplex mode for high speed modem

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-15 00:00:00 UTC
From: Tom Holden <tholden@toronto.cbc.ca>
Message-ID: <3263EBE8.2139@toronto.cbc.ca>
Source record: 101692
Cross-posted to: comp.modems,rec.radio.amateur.digital.misc,rec.radio.amateur.equipment,rec.radio.amateur.homebrew

Thanks to all who offered advice on my question.

In summary,

1. The designer of the Hayes Smartmodem 300/1200 modems and of the original AT command set confirmed that it was his intention to support a unidirectional test mode but is unaware that it was supported in subsequent Hayes modems or in thos eof other manufacture.

2. I have learned that high speed telephone modems go through an essential 'training' phase which, of necessity, requires a bi-directional path for negotiation.

3. Fax modems have been used for unidirectional data transfer at speeds of up to 9600 bps (V.29, V.27), in particular in Japan. A reference to the Japanese Packet Radio Users Group (PRUG) failed to turn up any further info.

4. Suggestions:
- use a short-haul 4-wire modem
- develop hardware/firmware specifically for application

Thanks to Rob Janssen, Jeff King, Gary Coffman, Dale Heatherington for the informative news posts and/or e-mails.

Regards,

Tom Holden, VE3MEO

> It is going to need retuned to go to those freqs, but you've also got to get
> rid of that 40 channel knob as far as tuning goes. How do you tune the band?
> Any help would be greatly appreciated... 73s Tyler N3SPDArticles on converting CB's to 10 meters were common in the 1970's and
are most available in back issues of 73 magazine. I think 73 still sells
a compendium of that series of articles. What killed off the enthusiasm
for cb-to-10 meter conversions was the FCC's type acceptance procedure
that has made it much more difficult (they cannot make it impossible) to
easily accomplish such a conversion.
Basic conversion procedure for the following generic CB units:
-Old "crystal/mixer" radios, usually having 2 banks of crystals near the
channel selector, 4 in one row and 6 in another:
These usually require swapping of the 6 crystals to get 23 or 24
channels into the desired new band... not recommended due to the
crystal cost, plus the fact that the channel spacing will not come out
the way you normally would like for a ham rig.

-Early synthesized CB radios: Depending on the rig you can either
change the reference crystal to one that will produce output in the 10
meter band or, again depending on the PLL chip involved, sometimes the
PLL chip can be re-programmed by un-grounding certain pins to allow
operation up into the 10 meter band with the original reference crystal
. On these radios you can install an IC/ counter circuit that can set
or even scan your new channels, use the original 40 channel switch for a
very limited set of channels you'll have to use a chart to tell what
freq you're on, or learn to "count binary" and use a row of dip or
other small switches to directly program the synthesizer.

-Latest CB rigs usually are potted inside epoxy etc. to frustrate
"re-programming" of the PLL. Some of these have "undocumented jumpers"
that can be cut or switched to allow out-of-band operation, some can be
shorn of their protective epoxy or other coating, and some have to be
used "as is" as a driver for an external transverter to operate on the
desired new band.

RF alignment, both TX and RX, is usually minor with any of the above
CB's, as the CB is already rather close to the 10 meter ham band, many
will put out usable power (close to a watt or so) with no realignment at
all, but retuning of course almost always produces much more
satisfactory results.

I have a lot of gell cell battery packs that were taken off UPS'. Do you know where I can find a good article on gell battery charging. I would even consider buying the charger from a commercial retailler if you know a good make.

My requirements are to be able to rechage a battery pack with a combined power rating of 200 watts/hour.

Thanks

Daniel

carl@ais.net (Carl Stevenson) wrote:

>Laura .. problem is the tubes are hard to find ...

Egad, man--tubes are a glut on the market!! The new Alltronics catalog lists hundreds of them, and Antique Radio Supply sells every tube I ever heard of, and loads more that look like they came from Mars. In my files are probably ten catalogs that offer tubes. Variable caps, well, that's more of a challenge, but the more generic sorts are out there. Fair Radio Sales is a good one to watch--but the point is that almost anything a homebrewer could want is in somebody's catalog, and if yer gonna play the game ya gotta pay the dues and get those catalogs.

This could be a golden age for building your own gear. The only challenge is to figure out how to make it happen.

Great. More government bullshit, to coddle us and protect us from ourselves. And then we won't have flea markets at all anymore! Or any other place to take a chance, and get a good price in exchange for the risk.

This 'wanting of someone else to be responsible' really frightens me. It's becoming so pervasive in our society. People need to get back to being willing to be responsible for the results of their own decisions.

You go to a flea market. You see something you think is a good deal. YOU have to decide whether its value to you at that price is worth the risk that it might not work.

It's a -flea market- for god's sake! It's not Sears. It's -supposed- to be full of junk that might not work, but is cheap enough to take a chance on. That's the fun part!

If you require that a vendor be willing to take back non-working gear, then make that clear to him up-front. If he'll give you a written warranty that it works, then you have an ethical and legal recourse if it doesn't.

If he's unwilling to give such a warranty, then -you- are responsible for walking away from the deal, or deciding to take a chance on it. He has done nothing wrong by refusing such a warranty.

There are many reasons he may not want to give a warranty, which have nothing to do with his ethics. Maybe he feels that at the price he's getting, he can't afford the time to mess with warranties, returns, paperwork, etc.. That's reasonable. If you don't agree, you don't have to buy it!

I know I feel that way when I sell an old 'scope for, say, $35. A warranty? For $35? Are you kidding me? For $350, maybe... But for $35, I never want to see it again.

Having said all that, I do appreciate when sellers state their knowledge of the condition on a tag (or in a newsgroup posting), even if it's just 'don't know, haven't tested it'. Any info at all helps the decision making process.

I've tried using a 670nm, 4mW laser diode. It doesn't work with any
photoresists that I've tried. The ones I tried were:
GC Electronics "Positive-type" resist (cat # 22-074)
M.G. Chemicals "KPR Photo Resist" (negative type, cat # 701)
Ever-Muse presensitized P.C.B. (Circuit Specialists Inc. cat # PP101)
I tried exposures as long as 30 minutes on one spot.

I, too, would like to hear from anyone who knows of a resist that *will* work
with a laser diode.

I found out that they moved to a small storefront in Cumings Park (around
the corner) but only sell new computer stuff there. Two stores away from
another similar store, near Comp USA (or whatever that big store on
Washington
St. is). They still sell surplus stuff in their NH store, but it is a haul
to get
there.

Probably for the best, as their prices were getting stratospheric and
selection
dwindling.

I moved to NY a couple of years ago but still visit the area once and a
while.
Any new places?

Oh, yes, try checking out Parker Products in Reading, not far away. He has
lots of solar stuff and a few old buildings full of JUNK. Mostly he likes
to do
mail order but if you talk nice he will let you scrounge around. Really
worth
it... some weird stuff like fiber optic image plates, raw pure silicon
chunks,
strange test equipment. Bring a good flashlight!!

Chargers have some form of current regulation,power supplies don't.
they also should also have some form of overcharge protection.

> Is there a way to modify the supply to be able to use it as a charger?

Put a current limiting resistor in series withe the battery. A good rule
of thumb is to chrge with 1/10th of the AH rating (IE: 7 AH= 700ma Charge
current.

If you think this, then you are merely presumptuous. Anyone who buys
something at a flea and expects it to work at home is a fool. To
obtain true "slack" you must NOT be a fool!! The trick is to pay
little enough for it that it is worth no more than its parts, and
where your intelligence and carefully acquired talent can either use
those parts for FAR more than their used cost, or even make it
function again!! If there were not idiots who drive the prices up with
their gullibility, then the prices would remain at that fair "slack"
value of only their exchange cost. Better to *impose* a basic intelligence
quotient in the used value of old electronics on all who come to buy
than limit what can be sold!! Should be a BIG SIGN up saying:
****
* "Items that don't work when you get home are entirely your fault *
* for being stupid enough to pay more for them than they are worth *
* if they were a pile of working and non-working parts on a table! *
* Your stupidity drives up prices on everyone else! If you want to *
* come here stupid then have enough sense to ask opinions of value *
* from people around you but don't believe anything you hear also! *
* IN THIS LIFE, YOU ARE ON YOUR OWN!!! DON'T PISS AND MOAN! THINK! *
****

This comming Sunday...
The seasons last....

*** !!!! WE ARE BACK IN THE GARAGE !!!! ****
so come rain or shine or super heat the Flea is on !!!

********* $1 buyers discount with hardcopy of this notice ********

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
October 20th, 1996
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >1000 cars!

Buyers admission is $4 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $10.00-each at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 146.52 and W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)
MIT Radio Society (W1MX)
Harvard Wireless Club (W1AF)

For more info / advanced reservations 617 253 3776

> looking something like a RF power transistor?

It will be some form of regulator. The simplest explanation is that the module contains a variable voltage regulator the output of which is governed by the 200 ohm pot. Thermal tracking to prevent runaway and maintain bias with device temperature is ensured by the package bolted to the heatsink having some form of temperature sensor.

Unless you really need class A, this device will be appropriate for good AB1 linearity.

Getting rid of the 3rd harmonic is best done with a filter, not by bias.

Hola Francisco. Yo no tengo el ICOM 706 pero he hecho un poco de contactos
con uno que mi amigo OH2BYS tiene. El 706 tiene buenas cosas y tambien
malas cosas.

Potencia de salida es sin duda 100 watios si la antenna no tiene
problemas. El 706 es muy pequeno, eso me gusta mucho. Es muy agradable
tener todas las bandas de 1.6 a 30 Mhz y 50 y 144 Mhz en una
radio. Las problemas que tiene estan: 1) los filtros de BLU estan muy
malos, 2) el equipo es un poco dificil de usar, por que tienes que
hacer que quieres "using menus" (perdon, mi castellano no es tan
bueno), 3) si hay grandisimas signales la radio tiene unos problemas.
Creo que el 706 no es para trabajar DX y concursos, pero es ok para
movil y contactos normales. En mi opinion el ICOM 706 es mejor que el
Kenwood TS 50.

>
>
>.... SMD is a godsend for the homebrewer. It is much easier than
>working with leaded parts.
>
Gary, I have to disagree. On a PCB leaded parts are *much* easier to work with, for the following reasons:

1. You don't need a magnifying glass to read their value (if you're lucky enough to have an SMD part with a value printed on it).

2. With a leaded part you just stick the leads through the holes, bend them slightly (so that the part doesn't fall out), turn the board over, and solder. With SMD the best technique I've seen is: tin one pad, grab part with a pair of tweezers, hold one end of part to this pad, heat with part & pad with soldering iron, press the part down as the solder melts so that the part is now flush with board, solder the other end of part (or other pins, if dealing with a device with more than 2 terminals). A technician at work is great doing this, but I *always* have problems with the part not sitting flush, or shifting slightly, or whatever! Oh, and a good pair of tweezers is a must, and the proper kind are hard to find.

And a good soldering iron is essential (Metcal stations are great).

3. With a through-hole part it's much easier to see if it was correctly soldered. I've had more problems over the years with SMD parts whose leads are not all soldered to pads than I have ever had with through-hole parts.

Having done lots of work with both SMD and leaded parts, I much prefer prototyping and building with leaded parts. Perhaps the only construction topic where SMD parts might be preferable to leaded is in rework - SMD's are much easier to remove.

If I were a kit manufacturer I'd think twice (or more!) about supplying kits with SMD's. Imagine the errors (and complaints) from incorrect part placements, alone!

Is this the one where cantankerous old men sell stuff that their
wives have been begging them to get rid of? One thing that I've found
is that *some* of the dealers there sell stuff that doesn't work and
refuse to take anything back. A better bet for old electronics gear
is probably the Electronics Superstore (in Waltham... or is it Woburn?).
They'll refund your money if you buy something from them and find that it
doesn't work when you get it home.

I'd like to see the dealers at the MIT flea market be held to this sort of
policy. If people don't have ethical standards, I say *impose* some on
them.

That's a shame. I wanted to buy more stuff from them for a 'mad scientist'-
style art installation. They had a ton of omnious looking meters/gauges/etc.

I'd still like to put some analog meters on my Linux box for things like
# of users and server load. But I know next to nothing about interfacing
electronic devices to a PC.

It'd be great to have the 'tripwire' program trigger a revolving red-light
on the top of the server for any suspected security breaches.

Just "publish" your HB rigs and stuff in this newsgroup, but post the
pictures, schematics, and PC board image files over in
alt.binaries.pictures.misc or 12hr or clocks
You'll have to hunt thru all the porno there to find the images, but
that's where binaries belong.
I essentially did this when I posted about the AM radio with sub-mini tubes.

>And Communications Transistor Corp. was purchased by Acrian,
>hence the "ACR" designation.

Thanks to your suggestion, I found out exactly what this part is. Note, it was obvious that it was some kind of bisaing component, but what exactly - and thereby how to use and set it.

The products are now manufactured by GHz Technology, Santa Clara, CA. The parts are diode-connected RF power transistor biasing networks. The BYI-1 is basically a diode (neg voltage TC) with a 0.7-ohm series resistor (pos TC) to provide about 1-ohm "dc" source impedance to the RF transistor(s).

The ZO-28/F in my amplifiers is more complex. It has a 2-diode string (to GND) to establish the bias voltage, with an emitter-follower to provide the desired low-Z source impedance (0.6 to 0.7 ohms) to the RF transistors. According to the data sheet, the part can consume up to 0.5A, which I observed.

Howdy.

I have been having fun designing and putting together
TRF's for the broadcast band using tubes such as the
older shouldered-style 6K7G's and such with plate
detectors. I wind the interstage coils with magnet
wire on old toilet paper tubes.

I'd like to try putting together a superhet this
time, using standard commercially built IF xformers,
since winding my own would be too much trouble.

I have construction details for winding IF xformers,
but not the patience.

I would like to try winding my oscillator coil,
this doesnt appear to be too difficult for a
Hartley style oscillator. I can get a commercial
coil, but was wondering if anyone else out
there likes to build old tube style radios
and what their experiences have been, especially
with designing the local oscillator.

Thanks, tony

Why not transmit on it? If it hasn't had vampire taps punched into
it, it's as good as RG-8 for transmitting, and better shielded too.
I'm real leery of any of it which *has* had vampire taps punched into
it, though. If they aren't potential arc paths, they have at least
destroyed any weatherproofing the cable may have had.

>vision and dexterity are not what they were)

I'm hyper-farsighted. That means I can't even see the darn little
parts without my glasses. I use one of two visual aids. In the field
when I'm doing repairs, I use an 8x B&L clip on jeweler's loupe. This
clips on the temple of your regular glasses and can pivot out of the
way. It is really slick, and lets me see the little buggers. It only
cost a few bucks from Jensen Tools. There are import copies of it
available, I see them at hamfests being sold by the imported tool
dealers, but they aren't as nicely made, and are only a few bucks
cheaper. Buy the good one.

At the bench I have an old B&L binocular microscope head which I've
adapted to a floating arm. It offers 10x and 30x and has a long working
focal distance so I can get my hands under it to work on the board.
These things were expensive as sin new, I saw one recently in a catalog
for over $1,000, but I got this one at Dayton for $75. The guy had
stands for them too, but he wanted more for the stand than for the
microscope head. I made my own stand.

To keep your hands steady, get a couple of sand bags, or wrist rests
for computer use. If you can rest your forearms, you'll be amazed
at how steady your hands become. Avoid too much coffee too. :-)

Now the other tools you need are pretty cheap. You need a static
hot air source. You can buy really expensive bench mount units,
but I find the little pocket Weller Pyropen Jr fine for all my
work. This is a butane powered soldering and hot air tool about
the size of an old fashioned fountain pen. There are soldering tips
available for it to allow you to work on conventional parts, and hot
air shrouds to allow you to use it with SMD. Weller makes a bigger
unit, called just the Pyropen. It is too big for most SMD work,
but with a heavy tip it is just right for installing PL-259
connectors outside in a wind storm. Don't get the two confused.

You'll also need some wooden toothpicks and some SMD solder paste.
And a pair of really sharply pointed tweezers. I'd also recomend

having a bit of modeling clay handy, some solderwick, and some
flux. Any anti-static protection you use for leaded parts will
work for SMD too.

I gave a brief description of how to use this stuff in another
message. If you need more detail, ask.

>small spark when attaching the positive alligator clip to the battery
>(with the supply off, of course).
>
>At that point the supply ceased to work. Further investigation found two
>open transistors in the supply.

Heh, heh, bad move. Always make sure the supply is on before connecting
it to the battery. Otherwise the reverse current flow from the battery
will pop things, as you learned. (Better quality supplies have reverse
protection diodes, but lots of them don't.)

>Questions:
>
>How does a battery charger differ from a power supply?

Not much at all for a *lead acid* battery charger. Both the lead
acid charger and the power supply are constant voltage devices.
But a *NiCd* charger is a different animal. NiCds should be charged
with a *constant current*. And that requires a different sort of
regulator. You can damage a NiCd by charging it with a constant
voltage. It can even explode.

>Is there a way to modify the supply to be able to use it as a charger?

Probably. It depends on the particular supply design, of course.
You'll have to alter the regulator to be a constant current regulator
rather than a constant voltage regulator. That's often possible, but
of course the utility of the unit as a regular power supply will be
lost.

>is probably the Electronics Superstore (in Waltham... or is it Woburn?).

The store is in Woburn. If you take 128/95 north, you get off at the
Woburn exit with the Jaguar/Toyota dealer, and loop around to the buildings
on the right by the exit ramp. They have a tall sign that's visible from
the highway.

>They'll refund your money if you buy something from them and find that it
>doesn't work when you get it home.
>I'd like to see the dealers at the MIT flea market be held to this sort of
>policy. If people don't have ethical standards, I say *impose* some on
>them.

I don't think that anyone could or should do anything like this.

If you, as a buyer, don't like the guarantees offered by a particular
seller, take your business elsewhere. I personally wouldn't depend on
verbal guarantees: get a business card and a receipt with a written
guarantee ("guaranteed working" or something). If the seller won't do
this, don't buy.

If you want the lower prices of "as-is, buyer beware" products, and you
have the knowledge to test function before you buy, or can fix afterwards,
enjoy the flea!

Hi, well someone set up a "separate" list for homebrew anyway heh?

Since I'm an avid homebrewer, I decided to join, WTH.

When I get time later, I'll put out some HB related stuff. Like a list
of my current projects, some wants, some questions etc.

Who else is already subscribed here? I send an email to the reflector
list server asking for "recipients" but it doesn't support that command.
Seems like we'll just have to introduce ourselves to each other.

73 till later,

Most of the fun in going to one of these is to buy that special
electronics item that you've wanted for years for next to nothing and
fixing it up. The best thing to do at these is assume everything needs
some sort of repair and make offers accordingly OR try it out and know
something about it before you buy. I wouldn't expect too many sellers to
agree with a refund policy even if it doesn't work after the sale.

Was that a PWM modulated rig? Or a conventional AM. And how much HV and bias did they use?

> a low mu triode or tetrode is much more linear
>
>The 3-500Z modulates quite nicely; typical distortion was under 1/2%.
>And no screen modulation to worry with.

The only PA that "modulates quite nicely" on AM is one that has the grid biased well into cutoff, and is driven into and out of plate current with very fast switching times.

That's why low or medium mu triodes are best, and they and tetrodes are operated well into class C when plate modulated. The requirement for low distortion linear modulation is a very non-linear RF conduction angle, because the tube has to follow square law power output power vs plate voltage traits. In other words, it has to be a good mixer rather than a linear amplifier.

As to using 3-500Z's at higher peak voltages, you'd better buy tubes with special testing. Last I heard, they were only hi-potting them to 8 kV. Unless you like to have tubes flash over I'd stay away from plate modulated voltages of over 3000 volts dc, because that would run the anode up to 6 kV with perfect coupling to the antenna. Loose or lighten the load, and high voltage could go much higher.

With the number of 3-500Z's I see flash over at 3600 volts dc anode voltage I'd sure not I'd even want to plate modulate (in a conventional system) them at that voltage. Especially in amateur service, where the tube cools off and sits dead for extended periods of time.

;^)

> c.) I haven't found a flea yet that you couldn't find 120VAC SOMEWHERE, If
> your spending more than a hundred dollars or so test it out before you buy.

Ah! If you are really serious about buying equipment, carry one of those little 200W 120VAC inverter bricks *with you* in your backpack, along with a cigarette socket to car battery clip adapter. Keep a small marine or gel-cell battery in your car (or with a friend who has a table).

This way, when you "roll up" on a good deal, ask the seller if you can borrow his cigarette lighter, or car battery, for a few minutes. If you can't use his car (and if you have time), run back and get your battery.

If he refuses...There's your answer!

I keep an 8-cell "AA" battery holder and an assortment of pigtail power connectors in my backpack. This way, I have an adjustable 1.5 to 12V power source to test things there on the spot (I'm planning on making a complete test box, complete with ammeter and current limiting).

I also carry a bunch of "AAA" and "C" cells in my backpack ("C" cells can be shimmed into "D" holders with a few coins between the batteries).

The same rule applies, If they won't let you test it.....etc,etc,etc.

Will they give you their business card or phone number? Make it clear you will not bother them unless absolutely necessary (secretly write down their license plate number, for "Justin Case").

Also carry a pocket DMM (This is a *must* for any flea enthusiast - NEVER buy batteries w/o testing them first!) and a small, bright flashlight (for "inspections").

Smell the equipment too! This can be a big clue as to it's condition. Does it smell like something blew up? Does it smell musty or moldy?

Another clue I have found is the physical condition of the unit. Sometimes the "cleanest" unit of the bunch is the one that failed prematurely and got stuffed on a shelf or back in the box. Whereas the "used looking" units were just taken

out of service.

More importantly than "functional", is "complete".

Nuthin' worse than getting something and finding out a piece, or a board, or a module, or an expensive or rare IC is missing. Now you know it's not functional, and there may be little chance of it even becoming functional again.

I always assume "dead" until happily proven otherwise. Follow your instincts! If you have doubts, there's a reason! I always concider the scrap value of the item also. Any expensive goodies in it? The power switch may be worth more than the item!

Some of my best deals were the "I don't know if it works...Oh,..five bucks" deals.

It's a gamble...Ya' win some, ya' loose some!

Caveat Emptor!!!!! <sp?>

(Let duh buyer beware!)

You guys are confusing Thinnet (RG58/U) cable with Thicknet (RG8/U) type.
I agree with Gary, I would not bother with Thicknet cable that's had
vampire taps. But if you find a length that's been used point-to-point,
fine. It might even have N connectors installed already!

Good luck.

1944. Re: FRG-7 probably has no PLL

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-16 00:00:00 UTC
From: Bob Mueller <IFF161@DJUKFA11.BITNET>
Message-ID: <96290.205015IFF161@DJUKFA11.BITNET>
Source record: 101655

There have been several postings on the FRG-7 receiver, concerning locking of the "PLL". I would appreciate anyone having the straight dope available correcting the following if I am wrong; I am hoping to stimulate reconsideration as I believe the FRG-7 has no PLL! (I am in no position to check this as I have no schematic around but)I vaguely recall a block diagram and seeing a Wadley loop.

If my memory has not failed me (and I do have a schematic for an FRG-7000, however that is related to the FRG-7), then the synthesizer is based on mixing harmonics from a 1 MHz quartz crystal with a tunable LC oscillator. The mixer products are filtered in a low frequency LC filter with enough selectivity to remove most of the mixed down harmonics except the desired one (about -70 dB for the nearest harmonics at +/- 1MHz). After this cleaning up and enough amplification the output of the filter amplifier is mixed with the above mentioned LC oscillator output in a way that drift of the LC oscillator is cancelled. In effect, you get the stability of the crystal oscillator, where all the hardware just functions as a harmonic selector.

A couple details; to get the rich supply of harmonics the quartz oscillator drives a needle pulse generator. The Wadley loop has been used in a couple other receivers, at least, like the Barlow Wadley, a portable covering from the broadcast band up to 30 MHz, and the Racal RA17 (I hope I have the correct model.) Also, the DX302, which closely resembles the FRG-7000, though there are small differences (looks almost like a carbon copy.)

To go on, once the filtered harmonic has been generated, it is mixed with the input signals to produce a low frequency range of outputs which I believe lie from 2 to 3 MHz in the FRG-7. Finally, there is a third conversion in what is practically a broadcast band table radio covering from 2 to 3 MHz instead of 525KHz to 1600 kHz. The local oscillator frequency is low enough to yield acceptable stability for the receivers purpose.

Please note: nowhere is there any mention of a PLL as is usually meant by this expression. The lock lamp would be telling you the LC oscillator is at a frequency somewhere in the bandpass of the filter amp., and not that a PLL is phase locked.

Anyone with a schematic; please verify and assure us all.

Bob

PS I hope I am not repeating something which has already been said. The system where I get this group tends to throw some messages away (I see answers for which I see no questions!)

> dsipe@calweb.com

10base5 is thicknet I think. If the cable is approximately the size of
RG-213 (RG-8) it is very good for VHF/UHF work. The losses are only
slightly worse than Beldon 9913, it has 4 shields (2 braid/2 foil) and
regular type N connectors will fit. The Yellow grade has a vinyl jacket
and there is an orangey-brown grade that is fluorocarbon based (teflon
FEP) and is fire resistant. Both are very cheap on the surplus market
(I have bought up to 300 ft rolls for 10c/ft). Warning if the cable is
used , look out for punctures where the Ethernet Taps were applied.
Carefully examine by feel every foot of the cable. They are very hard to
spot and when found should be taped carefully.

I did loss tests on this material a couple of years ago as a service to
a east coast surplus store. The results are as follows (actual tests on
a sample of cable):

Yellow PVC cable
loss/100ft = 1.7 dB @ 146 MHz, 2.3 dB @ 223, 3.4 dB @ 440
velocity factor = 0.79
Impedance = 50.5 +/- 0.5 ohms This is the actual variation noted within
the length being tested with a TDR.
length/lb = 8.6 ft (useful to estimate the length of a roll)

Orange tint FEP cable
Loss/100ft = 2.0dB @ 146, 2.6dB @ 223, 3.7dB @ 440
velocity factor = 0.77

Impedance = 51.5 +/- 0.5 ohms
Length/lb = 7.8 ft/lb

For comparison purposes the following data was taken from mfgrs data sheets

Beldon 9913 Needs special Type N Connector.
Loss/100 ft = 1.6 dB @ 146, 1.9 dB @ 223, 2.8 dB @ 440
Velocity factor = 0.84

Beldon 9914 (stranded center cond. I think) Needs special Type N conn.
Loss/100ft = 2.0 @ 146, 2.6 @ 223, 3.7 @ 440
Velocity factor = 0.78

RG-213
Loss/100ft = 2.7 @ 146, 3.5 @ 223, 5.0 @ 440
Velocity Factor = 0.66

I hope that this information will be useful to those who find this cable and would like to put it to use. I have been using several pieces of it for some time outside without any problems although it is not rated for exterior service and I have been warned by some folks that the jacket will fail. At the above mentioned surplus price I can replace it many times for the price of black stuff.

> Any help would be greatly appreciated... 73s Tyler N3SPD

The degree of difficulty depends on the rig. If you want to convert
one of the old rigs to 10M AM or FM it is fairly easy. I have
converted a number of them to 10M FM and added a repeator offset
switch. They work pretty well. I have also converted an old Sears
Road Talker 40 (SSB rig) to 10M. A bit more involved but nothing very
difficult. Not knowing what rig you want to convert, or if it will be
a FM or SSB conversion I am unable to provide much further info. In
most cases you need to change one crystal and peak up the transmitter
and receiver coils. In most cases you don't need to get rid of the 40
channel knob. There is a wealth of conversion information available.
In particular there was a complete series in 73 Magazine back in the
80's that covered conversions to CW, SSB, FM, AM, for use with
transverters, bandswitch modifications, adding scanner capabilities,
etc.. The converstions can be a lot of fun after the band returns.
We should see usable 10M conditions in the next 18 to 24 months.
During the last cycle I worked 78 countries using a converted "Chicken
Bander" in one winter without a lot of effort. I would suggest a trip
to the local library. Bob Heil (K9EID) also had a publication that
delt with CB to 10M FM converstions.

1951. 120VAC scanner from 12VDC

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-16 00:00:00 UTC
From: wjskelle@mtu.edu
Message-ID: <541okc$746@rock.me>
Source record: 101662

Howdy all:

I'd like to be able to run my home scanner this weekend at the SCCA PRO Rally so that I can listen to what's going on with the race while I'm marshalling.

I took this unit apart (Realistic PRO-2024) and measured the DC voltage off of the rectifier on the board. It was 13.5VDC, for all practical purposes automotive 12V. I installed a small coaxial power plug and soldered it directly to either side of the rectifier on the board. After plugging it in, I found that everything worked properly except for that it *DIDN'T RECEIVE*. I had my buddy verify this with his 2M right next to me, and it didn't pick up a thing. It's sitting in the house plugged into an AC source again with no problem.

I've reached the end of my knowedge on this subject -- any suggestions? Perhaps something ahead of the rectifier in the circuit isn't getting energized? No idea.

Thanks.

It's absolutly the right place to post.

>Did anybody ever convert a CB to 10 meters? Is it easily done?

Some rigs are easily converted others next to impossible. My personal
experence has been that the much older flea market CB's (usually $5 or so)
are the easiest.

You need to understand crystal mixing, if it has banks of crystals. And some
require only one crystal to be changed. Unless you have a fair amount of
homebrewing experience a CB conversion may prove difficult. You'll be better
off if you find a couple old CB's and then post a request for that specific
board. They are all quite different in the conversion process.

Come on, Gary. 'Fess up. How do you replace a 120 lead qfp ic?
I think SMD is a horror for anyone who wants to service a circuit
board. You might be able to replace a resistor, but servicing
any active device beyond a simple transistor is damn near impossible.

You could do "surface mount" style with regular DIP thru hole parts,
bend the leads out so it makes a flat footprint. Resistors and caps
and transistors are also easy. IF transformers are more difficult,
but one could bend the leads a little bit (make a little hook at the
lead end). I've done this and it worked. Or drill the holes for the
hard parts only.

I'd say there's a big difference between someone selling a plate for 50 cents
and someone selling testing equipment for ~$100. And who said anything about
the government? Not I. 'Twas you, knee-jerk boy.

>This 'wanting of someone else to be responsible' really frightens me. It's
>becoming so pervasive in our society. People need to get back to being
>willing to be responsible for the results of their own decisions.

Hoo boy... If I've triggered some latent derangement in you, then I
apologize to the readers of ne.general.

>It's a -flea market- for god's sake! It's not Sears. It's -supposed- to be

Again, we're not talking about 50 cent plates or $1 answering machines.
For my own part, I've simply decided not to give any of these vendors
my business. I think your neo-cortex needs calibrating if you think anyone
is calling for the government to intervene.

>Having said all that, I do appreciate when sellers state their knowledge of
>the condition on a tag (or in a newsgroup posting), even if it's just 'don't
>know, haven't tested it'. Any info at all helps the decision making process.

That's all I ask. In lieu of a blanket return policy...

Has to be neutralized and grid driven Chip, or else you need to modulate the driver also.

You have to run the tube way in cutoff, so the conduction angle is short. Peak anode voltage is about 5000 volts maximum, that's RF plus audio. Above that and you'll have a lot of tubes that might arc on occasion.

They will work, but a low mu triode or tetrode is much more linear when polate modulated and easier to adjust.

The Continental Electronics 314R-1 1 KW AM transmitter used a pair of
3-500Z's in plate modulated service. (An another as the 9 KV
Switching Modulator tube.) Broadband neutralization was accomplished
by an untuned split-secondary grid-coupling transformer. Grid swaming
and grid-leak bias were provided by the same wire-wound non-inductive
resistor.

> a low mu triode or tetrode is much more linear

The 3-500Z modulates quite nicely; typical distortion was under 1/2%.
And no screen modulation to worry with.

I have not, but other zero bias tubes were commonly plate modulated.
However, if you are operating grounded grid you must also plate modulate
the driving stage due to the feed thru power and when the plate voltage
approaches zero during modulation there will be excessive of grid current.

>

I prototype two ways: dead bug style and perf-board style. In neither case do I drill holes. Dead-bug style is damn fast, but perf board looks neater and is more mechanically stable. And best of all, the holes are already there!

In the past I've used a drill-press (although holes need to be fairly spot-on, through-hole parts will, in most cases, tolerate some slop). But why go through the hassle? Interestingly, in twenty years of engineering I've *never* seen an engineer prototype a circuit by actually laying out a PCB. It's *always* been wire-wrap, dead-bug, or perf-board. Some may do PCB proto's (probably for microstrip circuits?), but I've not come across them.

>
>Your SMD technique is *horrible*.

To each his own. It's actually a very common technique, it doesn't require any special tools (other than a *good* pair of tweezers and a tiny point on the soldering iron (again, Metcals are GREAT) - no solder paste, no hot-air tool), and it works *very* well. Our tech can assemble a board very quickly using this technique, and the board looks like it came off the manufacturing line. Hot-air is only used to remove large IC's.

But why use SMD parts for home-brew in the first place? Leaded parts are so much easier to use.

Message-ID: <199610161634.JAA13456@mail.ucsd.edu>
Source record: 101734

```
You may subscribe or unsubscribe to any of the various campus mailing
lists and the local redistributions of global mailing lists by sending
email to "listserv@ucsd". The commands understood by the listserver
program are:

HELP
lists this file. This is also sent whenever a message to
listserv is received from which no valid command could be
parsed.

HELP listname
lists a brief description of the maillist requested.

INDEX
lists all the maillists available for subscription.

LONGINDEX
lists all the maillists and their descriptions.

ADD listname
DELETE listname

ADD address listname
DELETE address listname
adds or deletes the given address to or from the list
specified. Mail is sent to the address given to confirm the
add or delete operation. For on-campus users, we strongly
recommend that you use your campus registered mailname when
subscribing (i.e., use the second form of the command which
includes a specification of the address). If you omit the
'address', the command will assume the mailbox that is in the
From: line of the message. Note that SUBSCRIBE is a synonym
for ADD; UNSUBSCRIBE for DELETE.

DELETE-ALL
UNSUBSCRIBE-ALL

DELETE-ALL address
UNSUBSCRIBE-ALL address
unsubscribes given address from all mailing lists. Mail is sent
the address given to confirm the deletions. If you omit
the 'address' the command will assume the mailbox that is in
the From: line of the message.

LIST
LIST address
lists all mailing lists to which the given address is subscribed.
```

If you omit the 'address' the command will assume the mailbox is
in the from line.

FAQ
FAQ listname
sends a list of "Frequently Asked Questions" for the appropriate
mailing list. The command "FAQ" by itself sends an index of
available FAQ's.

A command must be the first word on each line in the message. Lines
which do not start with a command word are ignored. If no commands were
found in the entire message, this help file will be returned to the
user. A single message may contain multiple commands; a separate
response will be sent for each.

Please note that it IS possible to add or delete someone else's
subscription to a mailing list. This facility is provided so that
subscribers may alter their own subscriptions from a new or different
computer account. There is therefore some potential for abuse; we
have chosen to limit this by mailing a confirmation notification
of any addition or deletion to the address added or deleted including
a copy of the message which requested the operation. At least you
can find out who's doing it to you.

Examples:

add sunusers

add ewombat foodlovers

delete wombat@cyberpunk.ucsd.edu connectionists

help eggbeaters

Note that although you would mail submissions to a campus mailing list by
addressing mail to e.g., sunusers@ucsd.edu. In a subscription request
you specify the name of the list simply (without the @ucsd part) as in
the first example above.

> I think SMD is a horror for anyone who wants to service a circuit
> board. You might be able to replace a resistor, but servicing
> any active device beyond a simple transistor is damn near impossible.

Like all technologies, surface mount can be impossible with the wrong tools, and dead simple with the right tools. If you are contemplating building or servicing equipment with 120 lead QFP ICs you will need to buy, beg, borrow or steal the correct equipment to tackle the job. Like the hot air guns and related stuff others have mentioned. Didn't people say similar things about transistors way back when? Or was it 14 pin DIP ICs?

For more ham-related stuff (e.g. from chip resistors and capacitors up to 20-or-so pin SOICs and PLCCs) a soldering iron with a tiny tip works well, though I too look covetously at hot air equipment.

My usual technique is to tin one pad, position the part, and hold it down with a long fingernail while I reflow the solder. Then solder the other connections. This way I have more fingers free (you need two to hold a toothpick), and get immediate feedback (OUCH!) if I overheat the part...

One thing to keep in mind at flea markets if you're shopping for electronics:

If you are at Mom & Pop's Flea Market and something doesn't work, you're better off buying it because chances are it's just a blown fuse or something easy.

If you are at the MIT Flea Market, assume that the sellers know a fair bit about electronics and it REALLY doesn't work. Then you buy it for parts. (Granted, if you can't test it and they don't indicate its' condition then you're stuck).

It's all a gamble and sometimes you come out a winner and sometimes you're stuck with another electic gizmo to gather dust in the workshop until your wife makes you clean it up and finally throw it away. (And don't accuse me of sexism... I am the daughter of a collector from hell and the wife-to-be of a physicist with a weakness for useless gadgets that don't work. SOMEBODY has to "encourage" the removal of gadgets... so there's room for new ones!)

:) Chris

Bob Mueller (IFF161@DJUKFA11.BITNET) wrote:
: A couple details; to get the rich supply of harmonics the quartz oscillator
: drives a needle pulse generator. The Wadley loop has been used in a couple
: other receivers, at least, like the Barlow Wadley, a portable covering from
: the broadcast band up to 30 MHz, and the Racal RA17 (I hope I have the correct
: model.) Also, the DX302, which closely resembles the FRG-7000, though there
: are small differences (looks almost like a carbon copy.)

In the RA17 the first signal conversion is an upconversion, a tunable high frequency oscillator mixes with the incoming HF to produce an IF of 45MHz. In a separate path, this same tunable oscillator output is mixed with the 1 MHz harmonics from the comb generator and the output from that mixing is used as the injection frequency for the second signal conversion which takes the 45MHz IF down to around 3 Mhz. The system is wideband (>1 Mhz) up to this point. The third signal conversion uses a high stability VFO to convert the 3 Mhz down to a 100Khz narrow band IF.

The "locking" occurs because the second signal mixer only gets any injection freqency drive when there is the high frequency VFO is at a frequency which will combine with a comb generator harmonic. This occurs each MHz as the oscillator is tuned.

The magic of the system is that the drift of the first high frequency oscillator is cancelled out because it is used once in an upconversion, and once in a down conversion. So long as the output from the first signal mixer stays in the bandwidth of the first 45 MHz If everything is cool.

Stephen

They did provide the app notes with my kit (AN762, 140 watt amp). Easy to put together, though one bias transistor they provided was not pin compatible with the board -- had to do some wire kludges to get the terminals wired :(. So you may have to use your brain, not just follow Heathkit-style instructions.

You also have to box it up, provide switching and output filters, etc.

--

It's amazing how questions about Ethernet coax seem to surface about every year or so, and I keep forgetting my loss chart at home. (sigh).

Suffice it to say, I was on the original design team, and the guy who actually did the design work on the coax is a ham. Yes, the thickwire Ethernet coax is 50.0 ohms, its loss characteristics and power handling capabilities are on a par, or better than RG-8/U, at least in the HF region and low VHF region. We didn't do extensive loss testing at VHF or above (no one in the group, including the manager, who is also a ham) had any VHF gear to bring in to work to try it :-). I have heard some anecdotal comments from network engineers from other companies that its performance at VHF and above is disappointing, and that appears to be due to the aluminum foil shield being the closest to the center conductor. Although the "shield" is four shields in one (foil-braid-foil-braid, looking from the inside going out), and provides fantastic protection against inward or outward signal leakage, it's kind of lousy with respect to skin effect at VHF.

So, you could probably run a kW through it on HF, and use it for phasing lines and other special things at VHF.

BTW, this applies to both the yellow PVC stuff and the translucent orange Teflon stuff, as well as the ugly purple "CI" cables with the TNC's on them.

Well, in your previous post you said:

"I'd like to see the dealers at the MIT flea market be held to this sort of
policy. If people don't have ethical standards, I say *impose* some on
them."

a.) Since your clearly reccomending that we *impose* ethical standards on
the MIT flea market vendors, The question of how you planned to do it would
certainly be in order.

b.) I don't plan on thinking just a *little* bit harder about how we could
implement such a policy, it's an absurd thought to begin with.

If your software can print to a PostScript file, you should
try taking this file to a typesetting studio. They're able
to use resolutions of up to 3600 dpi on transparent film
material that's sturdy enough to last you several batches
of PCBs. A roughly letter shaped page should be between $10
and $20.

Hope that helps,
Jens, DB9LL

Try a good heat gun and make an air director out of bent metal around
the air output of the gun. That and some small tools like dental picks
can work wonders with SMD devices. The fancy air desoldering tools
that the production department are using at my work are not much more
than that. Yes, they do have some temp control, but just be careful
and things will work out OK.

Message-ID: <3266E186.4D8B@3-cities.com>
Source record: 101601

Hi all,
I am looking for a used 137.xx Mhz WX satellite receiver. I built up the circuit boards for the decoder and interface board that were in 73 Amateur radio magazine several months ago (or was it longer?). I modified an old scanner, built a preamp, but I get a lot of noise and the picture resolution is not very good. I have looked at the hamtronics kits, but they were a little more than I wanted to spend. I would like to find a good receiver at a reasonable price. The age of the receiver is not important as long as it works. I would even be interested in a kit that someone built that dosen't work as long as it has the documents with it. I noted that in the magazine article some things weren't very clear, and if anyone else has built the circuits or attempted to build the circuits and can't get them to work I would be glad to share the info I learned.

If you look in the 1992 ARRL handbook, you will find a couple of
circuits and parts list/building instructions. I built the one that uses
a single MosFet. The one I built had a measured gain figure of approx
25db. The circuit wasn't hard to build, only has a handfull of parts and
substitution of parts is ok. 73's

Looking at the Belden catalogue - - their type 9880 yellow jacketed 10 base 5 coax has the following spec:
Imp 50 ohms, Vel Factor 78%, loss per 100 feet - 0.52 dB @ 10Mhz, 1.2 dB @ 50 Mhz. Sorry thats the highest frequency they list - but this is close enough to RG8 type figures to assume that performance will be similar. I wonder how well the yellow PVC jacket survives in the sunlight?

Oh yes, this is the one! I once bought a cd player for $50 that
didn't work. My life is OVER!!!! But then I got a sound card
with a Jazz 16 chip for $4 that works!!!! From the same guys
that were selling the maxxum external 28.8 modems for $10 (3 for
$25).

I love this flea market, but I hate the increase in admission
fees. I have two kids who always want to go (my daughter drools
over those soapstone animals and the lapel pins), and sometimes
I wonder if it wouldn't be worthwhile to just buy a seller's
ticket and troop the whole group in. God knows, *I've* got a
few old 286 boards and other odd junk that I could sell...

Oh, hey, and I bought a 3-button logitech jeep mouse (Natick Army
do-dah surplus) for $2.50 one time, that is still working!!!

Oscilloscopes for $25? What do you want one for? At those
prices, who cares? Old Commodore 64's? I liked showing my
daughter all those old CP/M Morrow and Zenith computes one guy
was selling, not to mention the Osbornes! A history of personal
computing, before your very eyes!

And my son bought a beautiful piano amp for $20 one month, that
works like a champ (he uses it to power his bass guitar).

>
>I'd like to see the dealers at the MIT flea market be held to this sort of

Xochi, don't buy anything. It's that simple. Sure, we'd like
everybody there to be on the up-and-up, and to stand behind
what they sell, and not everyone does. If you buy it as-is,
where is, you take a chance. Hey, last month I actually saw a

dealer give back the money a guy spent the month before on some item (I forget what) that didn't work.

w8jitom@aol.com (W8JI Tom) wrote:

>>The Continental Electronics 314R-1 1 KW AM transmitter
>Was that a PWM modulated rig? Or a conventional AM. And how much HV and
>bias did they use?

Same thing--insofar as the modulation of the anode is concerned. PWM rigs are high-level plate modulated. The modulated stage doesn't know the difference.

>The only PA that "modulates quite nicely" on AM is one that has the grid
>biased well into cutoff

That was my point about the grid-leak/grid-swamping resistor. You only need (for 5 KW PEP Output with a pair of 3-500Z's) about .8A of total grid current and a grid leak of ~250 Ohms: -200 VDC.

>As to using 3-500Z's at higher peak voltages, you'd better buy tubes with
>special testing. Last I heard, they were only hi-potting them to 8 kV.

That's about the supply voltage of the 314R-1: 8.5 KV. I've seen them glow when they got gassy but flashovers were not a significant problem unless the tube was defective. The normal anode voltage for carrier was about 3 KV; at 125% modulation, the theoretical value required is 6750; in practice a bit of peak stretch to about 6.9 KV was used to give near-perfect linearity.

>With the number of 3-500Z's I see flash over at 3600 volts dc anode
>voltage I'd sure not I'd even want to plate modulate (in a conventional
>system) them at that voltage.

I must tell you that I was surprized when Forrest Cummings chose a 3-500Z as the switch tube. But after almost twenty years of experience I can assure you, without reservation, that they will operate quite well up to 9 KV. (Those flashovers you've been seeing. Maybe they were triggered by cosmic rays. You probably just need a good cosmic-ray parasitic suppressor made with nichrome wire to stop those pesky flash overs.)

Long winded additional information:

1. Forrest used the 3CX3000A7 to switch 14 KV for the 5 KW PWM, the 315R-1. Bryan Cox, at Gates, used a 4CX3000A to switch 14.5 KV in his PDM 5 KW, the MW-5. PDM and PWM were different patents that were methods to minimize the capacitance at the switch tube output. In the classic circuit, supply voltage was applied to the switch tube anode so the switch tube cathode had to be floated; lots of capacitance

associated with that method. PDM put the full supply voltage on the PA anode and then modulated the positive PA cathode voltage. PWM put the PA anode at ground and modulated the negative cathode voltage. In both PWM and PDM the unwanted shunt capacitance at the modulator tube anode was lower by an order of magnitude than the unwanted capacitance at the modulator cathode of the classic circuit. Most of the unwanted capacitance to the modulator cathode in the classic circuit came from the transformers used to power the modulator tube filament, screen and grid.

2. All PDM/PWM transmitters are superior to older plate modulated transmitters that used audio amps, transformers, and reactors to superimpose the modulating voltage on the anode supply--except for one specific thing: operating into a high Q antenna system on MW, the PA anode often "sees" high impedances at one or the other of the sideband frequencies when the modulating frequency is high. High impedance at the sideband frequencies does not allow the PA to develop adequate sideband voltages to modulate the transmitter completely into the negative trough; the switching filter was no longer terminated properly. The old Class B [actually AB2] modulators had a lot of feedback around them and would drive the PA anode voltage down much closer to cutoff even when the sideband impedance was't right. [Of course the old modulators also were inefficient, used big heavy lossy distortion-introducing pieces of iron.] I wrote a tutorial paper on this for Broadcast Management/Engineering Magazine that was published back in October of '75. That paper largely plagarized the work of Bill McCarren of WCBS who had plagarized the work of Doherty. The band-aid we all came up with was to use a network between the antenna and transmitter with a phase shift that would make the anode impedances at the upper and lower sideband frequencies have roughly symmetrical impedances, hopefully with the real component lower than the anode impedance at carrier. (That's why you'll find an L-network section in the output network of every CEC Doherty amp we made up to 250 KW; we could rotate the sieband impedances around the Smith chart anyway we needed to in order to get the transmitter to work into bad loads to work.)

If you can "split" the battery and charge it as two
6 Volt batteries you have enough voltage (13.8) to make
two constant current devices (say a pair of LM317s each
with a 2 ohms/5 Watts current setting resistor) and charge
at about C/10 for 16 hours (or until the voltage peaks)
depending on the method you use for charge termination.

You can even put diodes between the current regulatoes
and the batteries :-).

>you want things with guarantees - go to Sears and pay $$$$$. I've found a
>lot of real neat things at flea markets and for cheap!

Yea, no kidding. I picked up a Kenwood UHF rig (circa 1992) for $35!! Did I
really expect it to work???

Actually all I had to do was ditch the surface mount micro (the one that did
all the DDS stuff) an replace it with a home brew PLL synthsizer, works
great!

I'm sure they guy that sold it to me didn't have a clue, so what should he
have said "Gee this is dead as a door nail and there's not a chance in hell
you'll ever get it working"????

Well I'm glad to see at least one person thinks it's not a lost art...now could one of you find gentleman (or ladies) point me in some good directions to build a base 2m radio? Just a tech now but wanting to learn about building one myself,etc. I keep looking for sources but really don't have much to go on.

TIA,
Grady

Hi Fred,

In article <544asb$7f0@library.airnews.net>, jfriley@iadfw.net (J. Fred Riley) writes:

>
>Same thing--insofar as the modulation of the anode is concerned. PWM
>rigs are high-level plate modulated. The modulated stage doesn't know
>the difference.

Unless I'm confused about the PWM system Harris is using, that's not correct. The PA is off and on in conventional PWM, while in conventional plate modulated AM there is a linear variation in voltage at the anode. There is a huge difference between them.
What is the waveshape at the PA anode? Is it switched at high frequencies, or a filtered time varying linear amplitude change with no off and on periods?

>>The only PA that "modulates quite nicely" on AM is one that has the grid
>>biased well into cutoff
>
>That was my point about the grid-leak/grid-swamping resistor. You
>only need (for 5 KW PEP Output with a pair of 3-500Z's) about .8A of
>total grid current and a grid leak of ~250 Ohms: -200 VDC.

Now I'm really surpised at Harris. .8 ampere of grid current, .4 ampere per tube for CCS operation at a very high grid voltage. A conventional grounded grid 3-500Z dissipates about 25 watts on the grid at 300 mA of current. While grid dissipation is a complex function not found from dc parameters, that seems like it's on the high side of safe.

Are you sure the PA isn't being pulsed on and off?

>>As to using 3-500Z's at higher peak voltages, you'd better buy tubes
with
>>special testing. Last I heard, they were only hi-potting them to 8 kV.

>was about 3 KV; at 125% modulation, the theoretical value required is
>6750; in practice a bit of peak stretch to about 6.9 KV was used to
>give near-perfect linearity.

Fluorescence can be due to glass impuritys, or gas. The color sometimes gives it away. Bottom line is that we have occasions where 3-500Z's fail (flash over) at 7 or 8 kV peak. It is worse with tubes used in

intermittent service, since the 3-500Z getters itself by anode temperature. If the anode isn't showing a little color, the getter isn't activated.

The worse time for a 3-500Z is at turn on. Especially if the tube has been run hot and then shut off for long periods. That's why so many SB-220's pop when turned on. THe cooling system was designed for 400 watts of tube dissipation total, so the seals run overtemperature when a stupid ham runs the amp in the SSB mode and cranks out 1000 watts of CW.

The PA is shut off and the seals leak a bit. The next time he turns it on he applies drive at high voltage (SSB position) and then "bang"....the tube flashes over.

That's the single largest failure in 3-500Z tubes. The rate of that failure is four time the next most common failure, anode weld failures.

>>With the number of 3-500Z's I see flash over at 3600 volts dc anode
>>voltage I'd sure not I'd even want to plate modulate (in a conventional
>>system) them at that voltage.
>
>I must tell you that I was surprized when Forrest Cummings chose a

>operate quite well up to 9 KV. (Those flashovers you've been seeing.
>Maybe they were triggered by cosmic rays. You probably just need a
>good cosmic-ray parasitic suppressor made with nichrome wire to stop
>those pesky flash overs.)

Yeah right, cosmic rays. And pigs can fly. If you put bat wings and eye of newt on the case it'll stop those pesky cosmic rays as well as all that nichrome.

I suppose this is a series PWM tube, and the voltage divides between the PWM tube and the PA. That reduces the 8 Kv considerably. It's the anode to cathode (actually grid) voltage that counts, not the supply to ground. I was talking about conventional AM.

>Long winded additional information:

deleted>

Anyway, few Hams will run PWM for many very good reasons. If the stage is a conventional AM plate modulated stage, the best tubes for linear AM modulation are tubes with very non-linear transfer characteristics. It has to be a very class C amplifier with no feedthrough (unless the driver is also modulated) that follows the square law voltage vs power output rules. PWM is totally different, even transistors work well with PWM.

Just put the two Henry 144 and 432 linears on the air
for some initial on-the-air tests.
They are both new.
When comparing these two new linears with the old
pair which are exactly the same type of henry linears
the screen cuurent on the new ones are HIGH!
Both linear have high currents according to the build-in
amp.meter.

ANy hints!

: Come on, Gary. 'Fess up. How do you replace a 120 lead qfp ic?
: I think SMD is a horror for anyone who wants to service a circuit
: board. You might be able to replace a resistor, but servicing
: any active device beyond a simple transistor is damn near impossible.

I'll tell you how you replace a 120-pin QFP part. Take a nice, sharp
X-Acto Knife and at the case of the device where the leads come in,
carefully cut the pins so the part comes out but the pins stay
soldered to the board. I can't emphasize C-A-R-E-F-U-L-L-Y enough
because if you go to fast, you can rip the etch off the board. Now,
take your soldering iron and some solder wick and run along the board
perpendicular to the pads and the pins will come off smoothly. Clean
up the board and solder on the new device.

BTW, this takes a nice, steady hand to do, but with just a little
practice it's not too bad. Here at work, we change out 240-pin QFP
parts and I've been asked on a number of occasions to do it. Loads
of fun!

In article <5409e9$dhs@news3.microserve.net>, tyler@cyberia.com says...

>Did anybody ever convert a CB to 10 meters? Is it easily done?

Well sir, I use a rig called Cobra 3900 that gave me USB/LSB/AM/NBFM and CW, that uses
a Motorola IC in the PLL ckt (MC145106 I gess). So, was more or less easy to set it's
range to 28...29.7MHz. Some re-tune at the receiver front-end, transmition driver/PA and
noise blanker circuits was needed. Today this is my 28MHz IF to an Yaesu FTV107 trans
verter on 6 and 2 meter and with a DEM 28 to 144MHz IF adaptor, 2 extra ports on 2 me -
ter to drive/receive on 1296, 2304 and 10GHz. But sorry, the scehmactics/procedures
are on my head(a weekend job). Other rig I play was a Midland (I missed the model) but
this one I modified to 6 meter, from 50.0 to 51.0 MHz. It's not so hard.
Best regards.

w8jitom@aol.com (W8JI Tom) wrote:

>Unless I'm confused about the PWM system

You're confusing two different systems. The Harris SX systems all use PDM switching regulators to vary the voltage on the drains--conventional AM. The DX series uses switched PA stages with power output levels of 1, 2 4, 8, 8,8,8,8,8,.....8. The RF input to each RF stage is a 50% duty cycle square wave and is not pulse width modulated; the number of RF stages varies to accomplish modulation. If the power level of the least significant bit is small enough, the resultant modulated waveform is quite clean.

The 314R-1 and 315R-1 that we made used PWM. We did build a real RF PWM transmitter, the 314F. It was a failure. The shorter RF pulses at carrier level meant that the overall efficiency couldn't compete with the RF switching or PDM/PWM transmitters where you're switching at the zero-current point. We couldn't afford to manufacture a transmitter that was only viable at 1 KW and have taken another approach.

>What is the waveshape at the PA anode? Is it switched at high frequencies,
>or a filtered time varying linear amplitude change with no off and on
>periods?

The 1 KW used a conventional PA output network so the PA conversion efficiency was about 82%. The 5 KW used a Tyler Circuit in the anode to increase the PA conversion efficiency to about 90%. The grid driving pulse on both transmitters was 120 degrees, i.e., zero third harmonic. The third harmonic trap in the anode let the anode turn on and off very rapidly resulting in reduced dissipation. (Most folks think only about the third harmonic when they see a Tyler circuit but it's second harmonic control that makes the output stage efficient--Tyler's paper is not an easy read but he's quite clear on what his objective is. In fact, in our high-power designs we juggle things until the net reactance of the third-harmonic trap and the output-network input capacitor are series resonant at the second harmonic.)

>Now I'm really surpised at Harris. .8 ampere of grid current, .4 ampere
>per tube for CCS operation at a very high grid voltage... seems like it's on the high side of safe.

Harris didn't do it; it was done at Collins. (Continental Electronics bought the broadcast products section of Collins in 1980.)

>Are you sure the PA isn't being pulsed on and off?

Yep.

>Fluorescence can be due to glass impuritys, or gas...If the anode isn't showing a little color, the getter isn't
>activated.

The florescence I understand. But I don't know why you say that about the anode & getter. The getter is indirectly heated by the filament, not the anode. That's why we want people to run their filaments at full voltage for one or two hundred hours; to keep the getter hot enough to scrub up the tubes initial outgassing that does occur. A lot of the gas does boil off the anode when it gets hot. Some from the grid. But mostly from the filament. (Once first hundred or two hundred hours are over we recommend that the filament voltage be turned down to the point where peak power starts to fall--about 4.6-4.7 Volts. The getter's getting enough heat to do what it needs to do. And the emission--read, consumption of di-tungsten carbide--is where it needs to be.)

>The worse time for a 3-500Z is at turn on...The PA is shut off and
>the seals leak a bit. The next time he turns it on
>he applies drive at high voltage (SSB position) and then "bang"....the tube flashes over.

Two points. First, I agree about turn on being a tough time for tubes. We got great life from our 3-500Z's. One of the things that helped was that we were using low-capacity transformers for the filaments cuz the filaments (of both the switch tube and the PA tubes) were operated at up to -9 KV relative to ground and their anodes. The physical separation of the primary and secondary windings limited the peak current capability and limits the rate of thermal expansion during turn on. That was a point I made in a previous e-mail: the better the control of turn-on current, the better your tube life is likely to be. That's true of 20 KW filaments. And it's just as true for 50-100 Watt filaments.

Second, we didn't use blower run-down to cool the filaments after filament voltage is removed. Before I came to CE, I'd never worked with many transmitters--certainly no big ones--that didn't have a blower run-down timer. I thought--a lot of people thought--it would kill tubes if you didn't have it. It doesn't help; it does hurt. Matter of fact, one time CBC (Canadian Broadcasting Corp.) refused to purchase some FM transmitters from us unless we added a cool-down timer. We figured, what the heck, might as well just change the design and make it a general product improvement. Well, as Gomer said, "Surpize, Surprize." The flipping filament life decreased by 20-30%!!! Turns out it ain't such a good idea to cool those filament seals off too quickly. And the guy who refused to put the run-down circuit in his designs back in the 70's, Lloyd Winter, had used enough templac to float a battle ship to make his point about filament seal temperature excursions. Lloyd always used to tell customers, when they asked about run down, that many transmitters had gone off with power failure and had no cool down. And no one could ever think of a single instance when the filament failed in such a circumstance.

Always the skeptic, I dug out the original engineering notebooks and, sure enough, you can not make a case for having a cool-down timer circuit. Plus, we have a gob of documentation to show how much it hurts.

>Yeah right, cosmic rays. And pigs can fly. If you put bat wings and eye of
>newt on the case it'll stop those pesky cosmic rays as well as all that
>nichrome.

Must be Barkhausen's ghost getting you. But, seriously, did you ever hear of the Crystal Gayle effect? Back when the 315R-1 was fairly new, Crystal Gayle had a record out called, "Don't It Make My Brown Eyes Blue." Well, sir, everytime old Crystal was hold "Bluuuuuuu", the 3CX3000A7's in the SwitchMod and the PA would go bang with a grid-filament short. Turned out to be a mechanical resonance in the grid (because of a missing spacer) that rattled that grid basket right into the filament. Shook that sucker bad. Maybe you got something similar going on--some little cabinet shimmy that might be at just the wrong frequency?

>I suppose this is a series PWM tube, and the voltage divides between the
>PWM tube and the PA. That reduces the 8 Kv considerably. It's the anode to
>cathode (actually grid) voltage that counts, not the supply to ground. I
>was talking about conventional AM.

So was I. There's 8.5 KV between the switch tube anode and grid. And there's at least 7 KV anode-to-grid on the PA tubes at the 125% modulation crest.

>Anyway, few Hams will run PWM for many very good reasons.

As far as I'm concerned, anyone who puts conventional AM on the ham bands is a lid, an infidel, and a CPI (Certified Practicing Idiot). But that doesn't mean that PWM doesn't have a future in ham radio. All the big transmitters we make are capable of SSB and ISB at no carrier to full carrier. We split the amplitude and Phase components of the SSB or ISB signal. The PWM modulator controls the PA's anode (or drain) voltage while the RF drive (the phase component which has been clipped by 60-100 db) is applied to the grid (or gate). The result is a very high-efficiency linear amplifier. This same approach could be applied to improve the efficiency of solid-state linear amplifiers; we can keep the output devices saturated so their efficiency is high. And the IGBT switching modulator's efficiency typically runs about 97%. The thing that held this up was the requirement that the modulator be DC coupled (properly, coupled to DC) from the amplitude detector and the requirement that the PA introduce no Incidental Phase Modulation as its DC voltage swings around. With feed-forward phase correction we can deal with the effects of the gate-capacity swing of the FET. The full-power, high-efficiency solid-state 1500 W ham amplifier may not be that far off. We can even directly rectify the power line and pitch the damn "plate" transformer. Float the PA off DC & AC ground the way God intended.

I just gotta say one more thing about conventional AM. I never, in my wildest dreams, thought that conventional AM would be in existence at this point in history. I thought it was on its way out thirty-five years ago. It is absolutely mind boggling that such an inefficient transmission mode could--and has--survived so long, so well. Wanna take a whack at explaining that.

These epistles are getting too long but I enjoy them.

Hello again to all:

Have received a donation to school ham club and as usual, it is sick.

The radio is an Azden PCS-4000. The PLL will not lock up.

I understand this is a common problem with this radio as it ages and the cure is to replace the VCO.

Has anyone done this? Or has anyone attempted to tweak it back and if so how?

We have manual but schematic is in bad shape.

Homebrewers---anybody ever "de-epoxied" a potted sub-assembly with any success?

any info welcomed

tnx and 73 Dan, KB1BG

>the repairman's job much easier.

Greetings. The topic has been lost here... "repairman" not the same as "equipment building and repair"... All you needed back then was a roll of solder, some flux, and a 60Watter... compare this to the $500+ Pace SMD rework station... Yes, a repairman IS equipped to repair and maybe even "homebrew" with SMD... but the average Joe "Ham" Sixpack is certainly not.

I can easily repair a DIP-based device... a $15 desoldering iron from RatShack and some experience gives me perfect unsolders 99% of the time... but I can not afford an SMD station.

Not that I don't improvise... I snip the legs off the SMD device with a Dremel and glue down the new device on top of the old and solder in 30ga wires from the old pads to the new.. or use a DIP... or just toss it.

[sorry, pet peeve]

Take care.

Daniel

If your looking for commercial chargers try the following:

The Battery Company
Ph 1 800-695-9482

Ratelle Communications
Ph (905) 844-4505

They both sell Power Sonic SLA batteries. Ratelle has this nice smart
charger for 6 & 12 V batteries that is good for the full range of AH
ratings available. The Battery Company may be able to send you some
literature that pertains to charging methods of "Powersonic
Batteries" which you may find useful for other makes too.

Hope this helps.

>what his objective is. In fact, in our high-power designs we juggle
>things until the net reactance of the third-harmonic trap and the
>output-network input capacitor are series resonant at the second
>harmonic.)

OK I'm sorta familiar with that. I've used such circuits, and even have one in my DX-100. The audio distortion went from 14% at 100 modulation to about 4% after modifying the grid and anode circuit. I used 3 rd and 5 th harmonic resonators in the 6146 leads, and bumped the bias up to 175 volts.

The overall efficiency was about 80%, and that rig has a crappy tank circuit.

>the anode & getter. The getter is indirectly heated by the filament,
>not the anode.

No, not in the metal anode 3-500Z. It's coated on the anode, and is only fully activated with some anode color.

As a matter of fact, one commercial PA with a 3-500Z driver was suffering chronic gasiing failures, the driver had to be replaced with a lower dissipation tube that showed a slight anode color, and the problem went away.

You can call Eimac and verify this. Most of the old 3-500Z engineers are gone, but Chazen or someone should be aware of it.

>power failure and had no cool down. And no one could ever think of a
>single instance when the filament failed in such a circumstance.

I agree completely. I've used enough templac to paint a car, and found the same thing. When I looked at the 220 for Heath, because of the inrush articles that popped up, I found the largest source of failure was seal damage from overheating. The constant RAPID thermal cycling of the poorly cooled pins was a problem in amplifiers run hard, and the anodes NEVER getting hot enough was the problem in amps run too easy!

I'm off track, but the point is too rapid of cooling or heating , either way, is bad. Too high temperature is a problem, as well as too cold.

>I just gotta say one more thing about conventional AM. I never, in my
>wildest dreams, thought that conventional AM would be in existence at
>this point in history. I thought it was on its way out thirty-five
>years ago. It is absolutely mind boggling that such an inefficient
>transmission mode could--and has--survived so long, so well. Wanna
>take a whack at explaining that.

Well, I dunno. I have a few AM rigs, but I've never made a single contact except on CW with them. I have them because I buy things I don't need, and like to play with stuff that was around when I was young hood...I mean novice. Some people just like old stuff, the AM rigs go well with my old Mustangs and Ramblers that I don't drive, since I do start em and listen to them idle.

Yesterday, I asked the President of our Ham Club if he thought it would be a good idea for me to do a presentation on how PCB's are fabricated. I've been an EE Design Engineer for over twenty years and have had quite a bit of experience in this area, both professional and hobby. He said he thought the subject would be to technical for our club. I guess we will just have to sit there and listen to more bellowing about 15 second DX QSO's.
It seems we've all become Amateur Radio Operators, not Radio Amateurs.

The ARRL Handbook plans for the grounded-grid 4-400 pair should
be a plug-in deal. This is in the 1981 and 1983 handbooks for sure.

I'm not sure what you should do about cathode bias -- the ARRL plans
used a big Zener diode (hard to find sometimes), but a more recent
Ham Radio Magazine article suggested using a 2N3055 with a Zener on it.
You could easily use an LM317 and a trim pot to have an adjustable
bias supply, and bias the 3-400s for maximum smoke.

I'm typing this from memory, so go easy on the flames, eh?

My personal experience has been that it's difficult to work with pqfps or other "fine pitch" parts with what I consider "hobby" tools. But Weller WTCP-type soldering stations are readily available at low prices on the surplus market, and with that sort of soldering tool and a bench-mounted magnifier/light, you can work with SOIC packs and resistors and capacitors, certainly. I've replaced pqfps with a Weller station, but occasionally get solder bridges that my old eyes have a hard time seeing; it isn't necessarily easy to get rid of such bridges as I've found from working under a stereo microscope -- then at least they are easier to see. To remove the old, you can cut leads and remove them one-by-one, heat the whole package and remove it all at once (not recommended without practicing on a board you don't care about), or melt the solder and pry up the lead, lead-by-lead. Clean the pads with solderwick, carefully position the new IC and tack leads at opposite corners, carefully check the position, and solder. No, 12-gauge solder and a 200 watt American Beauty aren't going to do the trick...

I do agree with Gary that making an SMT board, at least for anything down to 0805 R's and C's and 0.05" lead pitch ICs, is easier than doing the same circuit with thru-hole parts (thur hole board). For the most part, I don't have any reason to use fine-pitch parts in my homebrew designs anyway, except for a very few special things (perhaps like the latest family of Analog Devices DDS chips).

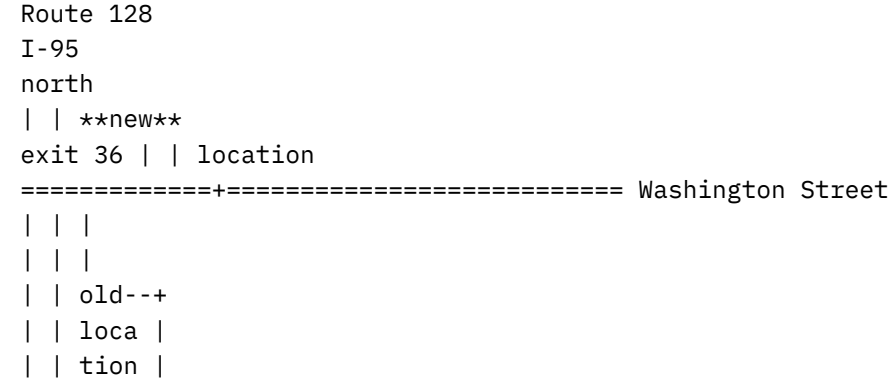
1. Unless otherwise negotiated with the seller, items bought at
virtually all flea markets, especially old or used equipment, are
sold 'as is' -- what you see is what you get. If you have a
problem with that, you should not be buying in such venues.

2. The Electronic Superstore in Woburn has moved and changed its
name to Electronic Planet. It is much smaller and more focused on
computer-related items. It is in a strip 'flex-space' center (i.e.,
quasi-industrial-retail building) on Washington Street just past
where you used to turn to get to their old location:



| | |
| |
south

There are two other interesting electronics dealers in the same little strip complex with Electronic Planet. One sells new components and tools, similar to You-Do-It, and the other is The Used Computer Store which sells just what its name implies.

The Electronic Superstore, in its larger incarnation complete with lots of industrial surplus and a collection of used test instruments remains in its entirety at its Manchester, New Hampshire location.

Cheers,
The Old Bear

My LIST of parts needed for building a tube xmtr:

1) CHassis - preferably 9 X 12 X 4" with base cover.

2) Matching box - sure, no problem, he he!

3) Tubes:

807
1625
12BY7
6146
6L6
6AQ5A
6CL6
OD3
OC3

4) Tube sockets: for all of the above tubes.

5) Transmitting Variable capacitors, low to medium power level:
30 pF (or 47 pF) trimmer
100 pF
150 pF
200 pF
365 pF

6) 2.5 mH RF Chokes 100 mA or 250 mA preferred.

7) Capacitors:
20 pF mica
22 pF mica
100 pF mica
180 pF mica
220 pF mica
270 pF mica
470 pF mica
.001 uF at 600 V and at 2000 V or at 1000 V
.005 uF at 600 V and at 1000 V
.01uF at 200 V and 600 V or 1000 V
.05uF at 1000 V or more

8) Resistors:
5 K 10 watts
22 K 1 watt or 2 watt
10 ohm 1 watt

330K 2 watt (need QTY 4-8)
27 K 1/2 watt or 1 watt
100 K 1/2 watt or 1 watt
47 ohm 1 watt
470 ohm 1/2 watt or 1 watt
220 k ohm 1/2 watt
2 K or 2.2 K 1 watt

9) Meter - prefer medium size 0-100 mA

10) FT-243 crystals

1805 - 1850 kHz
3515 - 3550 kHz
7010 - 7050 kHz

I only need xtals in THE ABOVE frequency ranges. Thanks.

Please call (301) 990-6070 or e-mail to:

w8jitom@aol.com (W8JI Tom) wrote:

> I used 3 rd and 5 th harmonic resonators

In every analysis I've done--or seen done--the addition of the 5 th harmonic resonator is a waste. The increase in efficiency is generally one percent or less. And the increased circuit losses and circuit complexity offset (cost) eliminate any savings.

>As a matter of fact, one commercial PA with a 3-500Z driver was suffering

I'll check in with him. It's so implausible that it might be true.

>I have a few AM rigs...because I buy things I don't need, and
>like to play with stuff that was around when I was young hood...I mean
>novice.

Well, that's cool; I understand it. But I was thinking about commercial AM and HF broadcasters when making my disparaging words about the use of AM. I mean, really! You could make a case for the diode detector in the 60's cuz it wuz real 'spensive. But it wasn't in the 70's. Look, we fight sales battles every damn day over the efficiency of transmitters. We've lost sales because one transmitter was a little more efficient that the one we were offering. But the broadcaster who is trying to buy the transmitter with the highest conversion efficiency is buying a transmitter for one of the least efficient communications methods know to mankind. How does AM survive as a medium of transmission. It just don't make no kind of sense to me. It ain't fidelity. It ain't spectrum efficiency. It ain't noise immunity. The only thing is about a dollar less cost in the receiver. Somedays I feel like we're still building buggy whips; nice buggy whips, but still buggy whips.

Hi,

I am looking to promote my homepage and I believe the best way to
do it is to have it added as a link from your home page.

What I suggest is that I add your banner and link to my home page and
in exchange, you add your banner and link to my home page.

For instance, I have developed some DTMF software, and let's say you
have developed some amateur related projects. On my home page I would
have:

Excellent link for electronic projects, which would take my visitor
from my page to your page.

On your page, there would be a banner "Excellent DTMF Decoding Software"
this would take your visitor from your page to my page.

So if this sounds like a good deal, email me your banner and homepage
location and I will do the same to you.

I only requirement is that your home page be somewhat electronic related.

Sent the information to KJ4UO@AOL.COM

THanks!

2046. Found - round & square chassis punches

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-18 00:00:00 UTC
From: dgf@netcom.com
Message-ID: <dgfDzHEs0.IJ3@netcom.com>
Source record: 101630

After a bit of research (with help from internet friends) I located a source for round and (1 size) square chassis punches. They are made by Q-MAX in the UK, and sold by FARNELL.

Next step was to find FARNELL. Turns out FARNELL and Newark are in some kind of venture/acquisition/merger/whatever. Anyway, I called my LOCAL Newark distributor (denver) and after a bit of convincing the rep found the FARNELL catalog and identified the punches to me.

They arrived (from stock, a couple of days later).

The sizes I purchased are round 3/8, 1/2, 9/16, 5/8, 3/4, 7/8 and 1" dia., and square 1"x1". The round punches were all in the $7-8 range, and the square punch was $36. The interesting thing is that GREENLEE still sells square punches but they are in the $100 each range. It appears that Q-MAX only makes a 1" square punch (maybe they'll add other sizes later?). There are many other round sizes, but only the one square size (too bad...)

The punches seem to be well made but I haven't tried to destroy one yet so I can't say what quality metal is used.

Gary,

Many thanks for your advice on SMD work. Equipment using SMDs may be more robust in the Cave Radio context (my particular interest) - I will give it a go.

Speaking of which, I just received a couple of samples of the AD 9850 DDS chip. Does anyone make any prototyping boards with surface-mount component landings on them? Hmmm, maybe if I find some bare PCB's with the appropriate surface-mount component landings, I can just cut them out of the board and glue them to a piece of copper-clad. Then solder the device to this piece of board and jumper wires to the rest of the circuitry (dead-bug or whatever).

: After plugging it in, I found that everything worked properly except for
: that it *DIDN'T RECEIVE*.

Good thing that you didn't cook your transformer. You were feeding
12VDC through the transformer secondary, which was basically a short
circuit.

My bet is that you were trying to check the scanner by running off of a
12V "wall wart" or other similarly current-limited device. If you
measured the voltage across the added jack, you probably would have read
3.5V or so, which is the voltage drop across the rectifier diodes. It's
possible that the "brains" are CMOS, with a 3-15V (or so) supply range,
so that's why the scanner appeared to work.

The receiver, OTOH, probably needs the whole 12V or so; otherwise, the
designer would have used a lower voltage. The 3V simply wasn't enough.

If you can, try breaking the circuit through the secondary of the power
transformer. If the xformer is not PCB mounted, you can probably
unsolder one of the secondary wires; connecting on the equipment side of
the rectifier is probably better in that you would not have the ~3V drop
through the rectifier. Most coaxial jacks are set up for an "either/or"
supply, so that the xformer is connected without a plug; disconnected
with a plug. This will give you a decent 12V-in connection.

Also.. be sure to fuse that lighter cord!

>I can easily repair a DIP-based device... a $15 desoldering iron
>from RatShack and some experience gives me perfect unsolders 99%
>of the time... but I can not afford an SMD station.

You appear to have a mistaken impression that SMD work requires
an expensive SMD rework station. In fact it does not. All you
really need is a source of static hot air and a few inexpensive
tools and supplies. A Weller Pyropen Jr is an inexpensive and
convienent source of static hot air. Add tweezers, toothpicks,
small bottles of solder paste and flux, a bit of solderwick, a
bit of modeling clay, and a jeweler's loupe, and you have a
complete SMD rework station that'll fit in a coat pocket and
will work in places where you can't even find an outlet to plug
in your soldering iron.

>Not that I don't improvise... I snip the legs off the SMD device
>with a Dremel and glue down the new device on top of the old and
>solder in 30ga wires from the old pads to the new.. or use a
>DIP... or just toss it.

Yuck! What an ugly technique. Why not just properly remove the
SMD device and replace it with a new one? It isn't hard to do
the repair correctly. You've just got to get over the one pin
at a time fixation soldering irons tend to promote.

It helped in the DX-100, although I can;t say how much without digging up the paper work. The largest change was getting the bias up, second largest a third harmonic resonator in the grid, and so on down the line. I wanted to do 90% or so, but never quite made it.

Remember one thing Fred, when the layout is crap the most esoteric things make a difference. Changing the impedance or length of a cable, or relocating a component can sometimes make a large performance change. The DX-100 is not particulary well laid out.

>I'll check in with him. It's so implausible that it might be true.

Get some gettering info on the 3-500Z, it explain some of those cosmic photon arcs. The 500Z absolutely getters via the anode coating, and the material is only fully activated at a dull red color. You can run the filament all week, and you won't de-gas the tube.

The worse thing in the world is to let a 3-500 sit around cold for months, and then apply full anode voltage. I've sucessfully de-gassed em with positive grid bias and low anode voltage, running the anode red at just over 1.5 kV for a half hour or so.

:
: Tim ka8ddz

don't know that circuit specifically... as a general rule it can be done,
results can be variable. Depending on the bands involved, you may want to

1) switch in the bare minimum of extra capacitance to lower the frequency

2) switch a completely different set of frequency-determining components

3) use a frequency doubler for harmonically related frequencies

4) just build completely separate VFO's for the different bands.
considering all the effort needed :-)

I am restoring some radios but have problems with repairing the aluminum coating.
Does anyone know what this clear, kind of yellow finish is that you see on most aluminum equipment chassis, and on aluminum antennas?

I don't think it is anodized, it looks like the aluminum parts are dipped in something, because you can still see the "drips" in the yellow coating.

Does any-one know that this "something" is that these parts are dipped in?

Thanks,

Loek LDHONT@ti.com

It sounds like the aluminum has been treated with alodine. Alodine makes
aluminum corrosion resistant. When I did my 90 days painting navy
aircraft, we applied it to bare aluminum with a sponge tipped applicator
and washed it off with water when the metal had turned the proper color.
It is also used on some of the mil spec electronics I work with.

We still use alodine in the aircraft industry. The stuff we use is a dry powder that we dissolve in water. We apply the resulting solution per your description. It protects the aluminum from corrosion, and it's electrically conductive. The alodine powder and solution react explosively with methyl-ethyl ketone.

If you want a ready to go preamp, ARR and SSB Electronics have
them. If you want to roll your own, check out the various Proceedings
of the Central States VHF Society volumes published by the ARRL.
GASFET preamp design has been covered extensively in those volumes.

That saves having to drill the board, but it isn't the real
reason you want to learn and use SMD technique. The real reason
is that leaded parts are becoming less easy to find because
manufacturers have increasingly changed over to SMD, and that
drives demand for the part manufacturers and distributors. In
10 years, I'd be real surprised if many parts were at all easy
to find in leaded configurations. That means we won't have much
choice if we want to build but to adopt SMD techniques.

Fortunately, those techniques are fairly easy to learn and apply.
And it doesn't cost much to equip yourself to do it. It just takes
a different way of thinking about how you mount and dismount
components, and a slightly different skill set for soldering
and desoldering.

>then. If I melt my finals, I'm coming after you... :-)

You haven't been paying attention. You don't vampire tap thinnet,
we're talking about thicknet cable here, and it is basically
RG-8 with a better shield.

Try "C and H Sales Co.", a surplus house. Last year they had at least 2
types: 400 wt., #23AWG, 3/16" od coil, 6" long, 27 ohms/coil @ $0.89
each.... or... 600 wt., #23, 8"long, 3/16 ", 18 ohms @ $1.09.

They are in Pasadena, CA - Phone (800) 325-9465 or (213) 681-4925.
The last time I dealt with them, the minimum order was $30. You can
order less, but like many, they added a $5 fee.

BTW, Be sure to use high-temp (nickel plated) crimp connectors, not the
"standard" type.

Contact MXM Industries, ROute 1 Box 156C, Smithville, Texas 78957, (512) 237-3906. They offer a product called the Simple RX -- can be built for any ham band from 80 meters through 20 meters. Could be put on other frequencies as well. It is a single conversion superhet based on the NE602 and has a small ceramic filter in the if. It can be tuned with a variable capacitor or a varactor, I don't know the kit price. The circuit board is about 1 inch by 3.5 inches. They also manufacture QRP transceiver kits.

Another way to remove a SMD from a PCB is to use a hot air gun.
You need enough heat to melt the solder, but it is quicker
and does less damage than cutting the leads with a knife.
On the down-side, it tends to de-solder adjacent components...

Cheers

-Mike

Thomas' original post hasn't made it here, but let me use this
as a way to comment to both of you.

The secret to working with SMD is in applying heat to *all* the
connections at the same time. The best way to do that is with
a static hot air source. The little Pyropen with suitable shrouds
works great for that for small and medium pin count packages.
For the really big parts, you need a bit more heat.

There are a couple of problems with using electrical heat guns.
There is too much hot oxygen in the output, and it can cause
problems with the joints due to near instant corrosion. Your
hot air source should be depleted of free oxygen. A torch does
this for you automatically since most of the free oxygen has
combined with the fuel, and the air stream is mostly fairly
inert combustion products.

The second problem with electric heat guns is that the air flow
is much too rapid. This will blow your parts around and won't
let surface tension align them automatically for you. Again,
the torch, with proper shroud design, can deliver a low speed
hot air flow precisely where you want it and in precisely the
correct amount for the work you are doing.

For the really big chips, I often use an ordinary hardware store
propane torch fitted with a homemade shroud. Of course you have

to work quickly (that's something you learn very early on with SMD) or you run the risk of scorching the board. You can regulate the temperature of the static air by the length of the shroud and by the distance from the board (you want to adjust the torch for a neutral flame, so you have to use other means to adjust the temperature of the hot air at the part). This is one of those things, like arc welding, which is easier to demonstrate than to explain. With practice, you pick up a feel for it, and can do clean work with no damage to the board.

This is not unique to "new" amateurs. The other day at the radio club I repaired a radio for a full call (has had a licence for 30+ years). The fault was a simple mechanical mis-alignment of the PTT plunger onto the switch. This same amateur needed help to determine that the lead fromn the battery charger has a break in it.

Mind you, he is a good operator
Mark.

One good source for 50 watt zener diodes is K2AW's Silicon Alley (the same fellow who's been advertising in QST forever). He stocks 12 different voltages and can get other voltages on special order. $7.50 each. And he's a great guy to deal with. His phone # is 516-334-7024. The usual disclaimer applies.

I guess we're going at this the wrong way. The resists are all
activated by UV, we're not going to get any action with red light.
I haven't ever heard of a diode UV laser, and I doubt even one of
the new blue LEDs would work. Looks like we need to make a collimated
UV light source that'll fit in the pen carrier. The only UV light I've
got is in the EPROM eraser, and that's too big. Does anyone know if
the cheap multimode plastic fiber cable will carry UV? If it will,
the light can be remote from the pen.

I know a little about electronics. I understand things like gates, transistors, etc, but I do not exactly have the knowledge to build a computer from scratch.

I also have very little money to devote to the world of Ham Radio. I would like to get a good transceiver for about $200, maybe $300

Could I build a good myself from a kit? Do they work well? I'm interested mainly in voice communications, a little CW (not a whole lot right now), using repeaters (and their autopatch), and possible RTTY/etc in the future.

Know of a good transceiver that I could buy or make?

What are the differences bewtween used and new in price and quality for transceivers?

What is the greatest distance a 2 meter signal will go at max. power on a Techinican License and average antenna? 200 miles? 1000 miles? Does this bounce of the atmosphere?

PLEASE EMAIL me your responses, I do not check usenet that often.

THANK YOU and 73!

>years ago. It is absolutely mind boggling that such an inefficient
>transmission mode could--and has--survived so long, so well. Wanna
>take a whack at explaining that.

Interesting discussion. I'd like to take a crack at this non-technical
point. A broadcaster survives by selling his product, an audience,
to his customer, the advertiser. As long as the installed base of
his product has AM receivers, he can't lure them with some other
modulation. They'll just switch to his competitors, and he'll starve.
(Well, if he switches to FM, he won't starve, but the FM allocations
in the lucrative markets are all taken.) And of course, the audience
isn't going to buy a receiver for a new kind of modulation as long
as there's no broadcaster sending it. So there's a chicken and egg
effect.

The only viable way out of this is a forced conversion by *all*
the players at once. This is what the FCC is doing to broadcast
TV. We're all going to have to change over to digital under the
same timetable. That avoids the problem of the audience switching
to those who don't changeover, because there won't be any. So
the audience has to buy new receivers, and other broadcasters
don't gain a competitive advantage when one station switches
to the new modulation because they'll all be switching.

There *is* another way, and that's to maintain backward
compatiblity. We did that when we went from B&W to color
television with NTSC. That was an awful kludge, and saddled
us with bad video for nearly 4 decades. We could have gone
PAL instead, but that would have obsoleted our product's
installed base of B&W receivers. If we'd done it all at once
like the digital switchover is going to be done, it would have
worked, but we were afraid to do that. We didn't know how
addictive TV was back then.

if we'd tried to work into it individually, we'd have starved
because the audience wouldn't have rushed out to buy dual
standard sets. Lots of UHF stations did starve until TV
sets were mandated to receive both VHF and UHF, and that
was a minor difference compared to an incompatibility between
B&W and color.

There is a new standard for AM broadcast lurking out there awaiting approval which is *transitionally* compatible. That's compatible digital. The broadcaster continues to broadcast AM while adding a digital broadcast on the same channel at the same time. It is cleverly designed so users with old receivers don't notice it, but users with new digital receivers can gain the benefit of it, stereo audio at least as good as FM with even better immunity to noise and fading, and requiring lots less power to broadcast (a 50 watt compatible digital signal has equivalent coverage to a 5,000 watt conventional AM signal).

I'm afraid, however, that if the FCC doesn't mandate that new receivers include the ability to receive the digital signal, the ultimate changeover of shutting down the conventional AM broadcast after a transition period will never occur. (AM radio isn't as addictive as TV, and the audience would just continue to switch to FM as they're already doing instead of buying a new radio just to receive AM digital.)

It's a hard problem to move a huge installed base to a new platform. We've seen that in the PC world, with aggravating limitations built into even our newest machines just so that they'll be backward compatible with old DOS software. Broadcast has the same sort of problems, but more so because the installed base is much larger, and much more firmly entrenched.

Yeah, when you're working with MMICs and the like, stripline is the
only way to go. Most of the RF stuff I've built in the last several
years has been for VHF+ until I reccently started my HF I/Q receiver
project. I just naturally continue to work with printed board.

I have done wirewrap for logic circuits, and occasionally dead bug
some circuit that doesn't lend itself well to board layout in the
space I have, but I like to avoid manual wiring as much as possible
and prefer to use a printed board right from the start. It usually
takes me less time to lay out and etch a board than it does to wire
up a circuit by hand. And there's less chance of a wiring error too.
I also think I have much better control of strays.

>>Your SMD technique is *horrible*.
>
>To each his own. It's actually a very common technique, it doesn't

>like it came off the manufacturing line. Hot-air is only used to
>remove large IC's.

Well, I suppose whatever works is Ok, but I find using hot air and
solder paste a lot easier. It works great and is very neat and fast.
I never have a solder bridge, and while it still takes a sharp eye
and steady hand, it's lots less demanding than trying to solder pad
by pad.

>But why use SMD parts for home-brew in the first place? Leaded parts
>are so much easier to use.

How much longer do you expect leaded parts to be around? Nearly
everything new is being built with SMD. Some parts are already
only available as SMD. Some heavy parts may continue to be
leaded, mostly for mechanical reasons, but I expect the majority
of parts to move pretty exclusively to the SMD form in a fairly

rapid fashion. We might as well get used to working with them
now.

2085. Good source for amplifier tips

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-20 00:00:00 UTC
From: wrt@eskimo.com
Message-ID: <326f3903.2636643@eskinews.eskimo.com>
Source record: 101569

If you're new at homebrewing amplifiers, you might want to check out AG6K's web site for a lot of good information:

http://www.vcnet.com/measures/

There is some personal stuff in there, since the author feels he was treated rather poorly by a well-known ham organization (I'm staying out of that), but the technical advice appears to be first-rate.

>Just curious.

Bill,

The FT-243s are the boxy military ones that are screwed together. If
you've got some you're not using I'm interested, since I've got all the
parts together to build a '40s-style TX and RX but no crystals!

Thanks and 73,

> Dave (KD5KZ) <dave.des@metronet.com>

Try Phillips-Tech Electronics in Scottsdale Az. 602-947-7700. Their
'96 catalog has downconverters starting at around $140.

I work with this stuff quite a bit as our ATV repeater output is
at 2.4GHz, but I have not seen any low cost "kits" in quite some
time. Most kits are in the more pricy Down East Microwave class
used for satellite and weak signal applications.

Your next best bet is the Ham fleamarkets. I see quite a few of
those old inexpensive downconverters and dishes for sale. I think
this is because many of the "Wireless Cable" services are going
belly up from competition from DSS. Services here in the San
Francisco Bay area are on the decline and I see a lot of the old
"Pirate" hardware floating around.

You, dear sir, are a man after my own heart. Norm Parker was once describing, over dinner, his involvement with committees that adopted NTSC (Never the same color), Multiplex FM Stereo (with its 22 db S/N penalty), and C-QUAM. When I opined that he had backed yet another failed system, I was accused of having verbally assaulted him.

The proof is in the pudding, as they say. I've seldom been in a PAL or SECAM country where the average TV didn't produce acceptable color. I've seldom been an NTSC set capable of displaying acceptable color. It is with a dark humor that I go into electronics superstores and look at the rows of demonstrators all tuned to the same program and all producing their own unique picture--each one wrong in its own way.

Norm defended the adoption of NTSC by citing PAL's inability to deal with saturated colors. When I noted that, in the real world, we don't deal with saturated colors, he was nonplussed. He used the same logic in dealing with AM Stereo: C-QUAM produced distortionless audio with a perfect wide-band diode detector. He ignored the effects of real-world IF strips on the phase modulation sidebands that can cause actual distortion to be higher that of a pure quadrature scheme. If technical merit had any meaning at all, Cliff Leitch's AM stereo system would have been adopted and we could have started reduction of the carrier level as early as 1990. Now, we're stuck. And I'm permanently prejudiced; I'll never vote for a backward-compatable scheme again.

>have much to go on.

Someone has already mentioned the TenTec kit. If a kit is acceptable to you, that's a good one. But if you really want to roll your own from scratch, we have to ask just how basic a radio will you accept?

If crystal control is acceptable, there are a number of designs in older issues of the Handbook and in RSGB publications. Many start with a varactor modulated crystal oscillator near 18 MHz and follow that by two triplers to reach 2m, and feed that into a driver and a PA transistor. This is a very straight forward design using only 5 transistors. 500 Hz deviation at the crystal frequency multiplies out to 4.5 kHz at 2m, just about perfect. (There are single chip transmitter subsystems available too, check out the Motorola MC2800 for example, and that can drive a hybrid brick, cutting your transmitter down to basically 2 chips, though the second will need a heatsink.)

For receive, the only sensible way is to use one of the single chip receiver subsystems. The older chips take 10.7 MHz RF and filter and hard limit it then downconvert it to 455 kHz for demodulation. You only need an oscillator and multiplier to feed a front end mixer that puts out 10.7 MHz RF when tuned to a 2m frequency. The subsystem chip does the rest. Some of the newer chips feature the first mixer and local oscillator on board as well. Motorola has an application note for such a single chip 2m receiver. You may want to put a helical resonator filtered preamp in front of it. Circuits for that can be found in the Handbook, the RSGB books, or the Proceedings of the Central States VHF Conferences.

Of course you need a mic amplifier and a output audio amplifier for the transmitter and receiver respectively as well, but this is a trivial one chip item in each case. (Though if you want to do it right you'll have some peak limiting in the mic amp to prevent over-deviation on voice peaks. There are special chips available to do this too.)

If you want to build a synthesized radio, however, you'll probably want to use a different topology for the transmitter. Usually, you'll want the VCO directly on-frequency at 2m. Since this isn't directly crystal controlled, you can modulate it enough to directly get 5 kHz deviation (if you've designed the loop filter correctly). This directly feeds the driver and PA stages, or a hybrid module like those used in commerical equipment, eliminating the tripler stages. But you need a divide by N stage, a phase detector, and a crystal reference oscillator to complete the PLL. Some control circuitry is also needed to control the divide by N stage so you can select different frequencies.

The same circuits can be used in the receiver to supply its LO, but offset 10.7 MHz to act as the conversion oscillator. Most of this is available on a chip today, so it isn't quite as complicated as it may sound. But designing a good PLL with low phase noise is still a non-trivial project for the scratch builder. There isn't a whole lot in the amateur literature about building PLLs. This is where consulting chip manufacturers' application notes and looking at the schematics and theory of operation of commercial equipment can be helpful.

If you want to scratch build, I suggest you start with the simpler crystal controlled radio. Later you can add a synthesizer as you gain experience. Or, you might choose to use a numerically controlled DDS at 18 MHz to feed the triplers. This may produce better results than using a PLL, and may be easier to do as well. DDS has been a hot topic in the amateur literature recently, with several good articles and construction projects.

If you just want to say "I built it myself", then buy the TenTec kit. It has most of the features of the Japanese radios, has an excellent manual to lead you through construction, and works quite well when you're finished. While this isn't as educational as scratch building, you will become familiar with one way a PLL radio can be designed. (If you really want an education, buy the Ramsey kit and learn how a PLL radio should *not* be designed.)

An intermediate choice between those two extremes is to buy and build the Hamtronics kits. They are crystal controlled receiver and transmitter kits. They work Ok, and can save you having to scrounge the parts for your own design. The instructions are rather sparse, and the circuits don't always work as they should, so there's more challenge to get them running than with the TenTec kit. (But they're much less of a challenge to get working right than the Ramsey kit.)

In response to Ed's question...

YES it is! But we do need to make it clear to Washington D.C. if we
hope not to lose any more frequencies. It appears that the loss for
frequencies is increasing at an alarming rate lately.

See another of my posts about electric hot air guns. Hot oxygen is
corrosive, a torch is better because the air stream is mostly inert
combustion products. As to de-soldering surrounding components,
use of a hot air shroud on the hot air source, and use of modeling
clay to form protective heat dams, can deal with that.

>
>73, Bill W7LZP

Hi Bill,

First, all of Measures stuff was sent out by QST to several independent engineers for review.

Unfavorable comments were received from a list that read like who's who in RF engineering. It included engineers at Harris, Collins, Eimac, NASA and many other places. Out of dozens of replys, not one was favorable. Measures uses his web page to lay blame on Dick Ehrhorn, QST, and even me.

The only thing QST handled poorly was printing Measures flawed theories without proper review.

I offered, and still offer, to debate Mr. Measures or his representative in an open forum on Internet or in any publication. The only restriction I require is we discuss one point at a time, and that both of us refrain from wild personal accusations about manufacturers, other people, or each other. In short, the only restriction is the debate be kept to technical issues, and not be full of personal attacks or wild conspiracy theories.

I would advise anyone looking for "good" amplifier tips to read Eimac's "Care and Feeding of Power Grid Tubes, or many of the excellent articles from QST or the Handbook back when proper technical editing was in vogue and people understood tubes, like in the 70's and earlier.

While many of Measures' suggestions are harmless, some are not. Some suggestions will put the user in harm's way, or cause equipment damage. I'd hate to see someone ruin a $500 tube, or worse yet hurt themselves, following poor advice.

73, Tom

Excellent points. It's not surprising that AM broadcast still exists.
It still works. We still have FM stereo (technically inferior to other
systems), NTSC (nuff said below), the current CD system, PCs, VHS
videotape, internal combustion engines.... ad naseum. AM is just one
of many things that shouldn't exist but do mainly due to inertia.

Large infrastructure systems tend to change slowly.

Interesting discussion about getters and the 3-500Z and so on. I know of one TL922 amp with a pair of 3-500Zs in which was left turned on for about a 6 month stretch but without being significantly used as an RF amp. The amp will now only do about 500W out and, as no expert and on anecdotal evidence, I put this down to some form of poisioning of the heaters. Is this a non-reversable process that a few hours of giving the amp a good caning won't cure, and do people have any comments on the merits of running the heaters at overvoltage for a short time to burn the rubbish off the surface?

Greetings. Ever check size of a good TIFF of a schematics? 4-5MB... figure compressing to a JPG ... maybe 100-200KB... how many of these can you fit in a 1MB account? :-| The ONLY way you can get this scheme off the ground is to get an .edu to dedicate a few dozen MB or some commercial company do some "PR" :-)

Take care.

2101. Handheld scope

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-21 00:00:00 UTC
From: "D. J. Wang (N2YKP)" <ddw2@lehigh.edu>
Message-ID: <326B7DF0.6E16@lehigh.edu>
Source record: 101488

Greetings,
I found an interesting ad in EDN magazine and asked for further info
regarding an handheld scope I thought may be of interest to people in
this news group:

----------osziFOX
(R) An universal service oscilloscope

Once oscilloscopes were heavy and clumsy to handle but over the years
they
have got
smaller and smaller. The latest development in this field has just
appeared:
a memory
oscilloscope with a build in voltmeter in a handy, slim housing,
scarcely
longer than a
pencil and about as thick as your thumb.

Despite its small size, its performance can match that of a service
oscilloscope. With a
sampling rate of up to 20 MHz, even signals in microprocessor
circuits
can be
recorded.The small housing means that the LC-Display is
correspondingly small. Its relatively large matrix dots, however,
make
the display legible even at relatively long distances. The background
lighting further enhances the display.

The osziFOX has many uses in the worlds of work and hobby. It can be
used for
taking
measurements in:

amplifiers, digital circuits, telephone installations, hobby
electronics,
production-line tests, servicing, on-the-spot measuring.

With the osziFOX-Software for MS-DOS or MS-WINDOWS and the serial cable,
the
recorded signals can be shown simultaneously on a PC screen
[IBM-compatible] via the serial interface. For documentation purposes,
the
recorded signals can be stored on disk, or the signal image can be
printed

out.

Connection to the supply voltage [+9VDC...+13VDC] is via the cable and clips
provided or from an optional AC adapter.

Technical Data

Sampling rates: 50ns, 100ns, 0.5us...1ms
Input divider: 1V, 10V and 100V
Input coupling: AC, DC and Groung [GND]
Input impedance: 1Mohm
Trigger: +/-INTERN, +/-EXTERN, AUTO
Trigger level: six different Levels
Trigger enable: Continuous or Single
Voltmeter: AC or DC Voltmeter
LC-Display: 16 x 32 pixel resolution
LED-background illuminated, green
Operating voltage: +9VDC...+13VDC external, 10mA....90mA
For PC operation: MS-WINDOWS or MS-DOS-Version
At least 128KB main memory, RS232 interface
VGA or EGA monitor, optional printer
Dimensions: 165mm x 33mm x 20mm
Weight: approx. 85g
Warranty: 3 years

Distributor Pricing 9/1996 20 MHz Oscilloscope "osziFOX"

Sample Unit USD 99.99 at your local Radio Shack Store available.
100-400 pcs USD 72.50
500-900 pcs USD 69.95
1000-2400 pcs USD 68.00
2500-4900 pcs USD 67.65
5000-9900 pcs USD 67.30
10000 and more pcs USD 65.00

Shipment includes osziFOX(R) V3.0 Software for MS-DOS and MS-WINDOWS 31/2",
Trigger Cable and Clip, Ground Cable and Clip, Power Cable with alligator
clips, Serial Cable. Manual is provided in the Help File of the software for
MS-Windows.
Prices do also include duties and delivery costs to U.S. Border.

Fixed Retail Price USD 99.99 + Tax + Shipping/Handling

Packaged in Master Package of 100pcs available only (No gift box).

Payment terms are 50% in advance and 50% on delivery.
Delivery terms: Small quantities available on stock. Up to 12 weeks on huge
quantities.

Source record: 101489

I've been building the G4BWE 80m / 20m superhet receiver. It has a xtal filter made up from 8.87...MHz colour tv xtals (8 of them). As I don't have the facilities for accurately checking their frequency I was thinking of using a 9MHz filter from somewhere. Is this alright (the 5-5.5 MHz VFO should be able to deal with the IF change no problems) from the point of view of input and output impedances and other stuff like that. If so then where in the UK would I be able to get these xtal filters? TIA

Greetings all,

I've been kicking around the notion of controlling my old Kenwood Ts-440 HF rig with my PC. I've found plenty of shareware programs that handle the PC end of things, but I'm a little shy about forking over 100+ bucks to get the official Kenwood interface box (especially since we have a new baby at home now). Are there kits and/or schematics for boards out there which could replace the Kenwood box? I assume it's just a TTL to RS-232 interface, but I'm not sure. Also, what about the EPROMs which plug into the radio? Are those only available on the used market these days? I'd be happy to hear from anyone who uses PC control for a '440 (homebrewed or otherwise). Thanks a lot.

IN one of the last (the 1993 issue, I think) ARRL handbooks, there is a
charger for Gel cell batteries. It uses standard components troughout
and should be easy to adapt for Your Ah-ratings.

Another approach is to use a special IC from Unitrode (the UC3906, not
shure about the number). They have a webpage with complete datasheets.

Very easy to use IC, but quite expensive.

The external box for the '440 is nothing more than a level translator.
converts TTL on the radio side to RS-232 on the computer side. You
can use the Maxim MAX232 series ICs to do that.

I'm not aware of any EPROMS that need to installed in the radio.
In my 440, the only ICs that needed to be installed were an 8255
UART and a 4040 ripple counter if memory serves.

Good Luck

>off the surface?
>
>Andy Cook, G4PIQ.

Hi Andy,

I'm not completely positive of this, but I believe the 922 has series connected filaments and also runs them a bit hot. Both are very undesirable.

The filaments have probably already been completely de-carburized through out the structure by the long filament hours, or perhaps contaminated by the long filament operation with a cold anode and no gettering.

All you can do is try, they'll either get worse, stay the same, or improve...hi.

By the way, the reason series connected filamnents are so bad is the thinnest most fragile filament has the highest dissipation at turn on. It also is the quickest filament to heat, and the temperature difference causes the resistance of the thinnest filament to heat even more rapidly than the heavier filament in the colded filament tube.

The filament less likely to stand the thermal shock (it's virtually all thermal, not magnetic) receives the most turn on power, and the most rapid heating.

Another problem is the operating bias switches back and forth between the tubes at a power line rate, with the total bias shift almost 28 volts from the extreme end to end of the directly heated filament chain (with 5 volt filament tubes). That always causes some unwanted and unnecessary noise or hum on a pure carrier.

Series connected filaments are bad enough in Christmas tree lghts, but they are idiotic in a power amplifier.

I am trying to initialize an 82510 in an embedded design and am having great problems. I am simply trying to put the 82510 in the 8250 compatability mode and set the baud rate to 1200 baud. I have read all the appropriate data books and this seems like a simple proposition. Sometimes the chip initializes correctly and sometimes it does not. Does anyone have any ideas? Here is my 'C' code:

```
/*-----------------------------------------------------------*/

GIRBANK = 0x00; /* Switch to bank 0...8250 mode */
LCR = 0x80; /* Setup for baud selection */
BAL = 0xa0; /* Set 1200 baud...with 16 Mhz crystal */
BAH = 0x01;
LCR = 0x03; /* 8 data bits, no parity */

while(1) {
/* Wait til TX buffer empty */
while( ((value = LSR) & 0x40) == 0);

TXD = 0x41; /* Write the character 'A' to port */
}

/*-----------------------------------------------------------*/
```

Thanks,

Steve

I came across a British military "boatanchor" recently that used this
series of tubes, the A43R transceiver. Also, I worked in the 60's and
70's on a navigation system (Decca Hifix) that used these extensively.
They were also used in the UK as well for "deaf-aids" in the 50s, my
grandad had one which needed regular battery changes! If I ever get any
info on the A43R I might be chasing you for some spares!

Some resists require handling under safelights - these will be exposed by blue not to mention UV light - so blue LEDS might have a chance of being useful. A company makes a little UV-curer, for things like bonding teeth and doublet lenses. The UV source is a quartz-halogen bulb, filtered for near UV, and delivered with a small length of fiber-bundle, I think glass-based (since the bulb runs HOT). But unless you do something special to change it, glass and all plastics except polycarbonate are transparent in the near-UV, ~320-400 nm

>I haven't ever heard of a diode UV laser, and I doubt even one of
>the new blue LEDs would work. Looks like we need to make a collimated
>UV light source that'll fit in the pen carrier. The only UV light I've
>got is in the EPROM eraser, and that's too big. Does anyone know if
>the cheap multimode plastic fiber cable will carry UV? If it will,
>the light can be remote from the pen.

Spencer Gifts (and Edmund Scientific) black lights are only a few tens of dollars, and emit wads of light in the 360 nm neighborhood. The handheld minerallights are smaller, a bit more intense, and much more expensive. Neither is collimated.

UV diode lasers remain to be invented, and after that will be at least another decade before they are as cheap as the red ones are now, if ever.

Other UV lasers tend to be big and/or expensive. I've built a few nitrogen lasers - 337 nm - but it would be quite a project to fold one into a photoresist exposure station. Commercial UV lasers are all more than a few kilobucks.

UV LEDs also remain to be invented, but will come on the scene first.

This IS the correct place for this question.

> Did anybody ever convert a CB to 10 meters?

I've converted DOZENS of them over the years.

> Is it easily done?

Yes, if you know what you're doing. You didn't say what kind you have,
and what you want to do with it.

> (nothing is ever easily done, but is it easier than making Hillary
> Clinton a nice lady?)

No comment... I'm a Republican... take a guess at my opinion! ;)

> It is going to need retuned to go to those freqs,

Yes, alignment of the VCO, receiver front end, and transmitter chain is
required after conversion, but this is not difficult to accomplish, IF
you know what you're doing.

> but you've also got to get rid of that 40 channel knob as far as tuning
> goes. How do you tune the band?

You just use the 40 channel knob. You could build a VFO, but it's not
worth the trouble. If you want VFO tuning, buy an HR-2510, HTX-100, or
something along those lines.

> Any help would be greatly appreciated... 73s Tyler N3SPD

Locate someone (another ham, library, etc) who has a good collection of
"73" magazine. Search the issues from about 1976 through about 1984 or
so (give or take a couple of years). They ran a continuing series of
articles entitled "CB To Ten". See also QST, August 1981, plus other
issues, and other magazines. In general, this sort of thing became a
popular thing to do about 1980 +/- a couple of years. There is a store
in Arizona called CBCI (that stands for CB City International). It is
run by Lou Franklin, K6NH, a long-time bootleg CBer who caters to other
bootleg CBers, but expanded his product line to suck in the hams. His
prices (when I checked a few years ago) were really OBSCENE, but he has
a very complete product line with virtually anything you could want to
modify a CB radio. Look in any recent issue of QST for his ad. If you

can find the Sams Photofacts book on your CB, buy it. The information
is invaluable, and the schematics are large and easy to read.

Other questions? email me privately.

2117. Need Measurements Corp. Manual

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-21 00:00:00 UTC
From: Mark Hillier <Mark@HVWTech.com>
Message-ID: <326BF330.438@HVWTech.com>
Source record: 101504

I am looking for a manual for a Measurements Corp. model 58 UHF Field Strength meter.

I would prefer an original manual but would be glad to get a photocopy if an original is not available.

Will, of course, gladly pay for manual, copies, postage etc. Pls. reply via email:

Mark@HVWTech.com

Thanks.

I'd like to see a newsgroup for QRPers. I mentioned this to a couple
of friends who are QRP-L members. They both said this idea has been
brought up many times, and each time, it was shot down in flames. I
can't see why, but that's what happened.

Some years ago I often visited a manufacturing subcontractor in the Southeast who used hot air for re-attaching SMD rework. These looked like big soldering pencils sans tip, and attached to both the AC line and the compressed-air lines that ran throughout the facility. They didn't seem to have a problem with their joints, so I don't think I'd worry too much about hot-air induced corrosion problems. Take a stroll through an electronics tool catalog (Techni-Tool, for example) and you'll see any number of hot-air SMD soldering tools.

If I were to use hot-air rather than an iron, I'd buy one specifically made for SMD work. With them you can control the heat, and they come with different size directors (deflectors?). I don't know how well a standard hot-air gun would work, but you can't control their heat and they're big and unwieldly. Gary's idea of the Weller propane device is a good one, too.

Then again, Friday I visited our manufacturing subcontractor (local here in the Silicon Valley), and they used Metcal stations throughout (this is a fancy soldering iron). At home I use my Weller iron (I'd rather have a Metcal - I'm keeping my eyes open at the swapmeets!).

In other words, use whatever works best for you. If you use an iron, there are three things that you'll need. 1) Very small tip, 2) very thin gauge solder, 3) tweezers. The method Laura mentioned earlier is a common one for soldering SMD devices and works quite well (tin one pad, hold part to this pad and reflow solder, then solder all other pads). You don't need to invest lots of money for new equipment.

Oh, and make sure your bench is well lit!

> fit in a 1MB account? :-| The ONLY way you can get this scheme off
> the ground is to get an .edu to dedicate a few dozen MB or some
> commercial company do some "PR" :-)

All it takes is a little negotiation...Mindspring for instance offers 10MB of space for your WebPage. Mindspring is a VERY large ISP that provides access in lots of SouthEastern Cities. If you have a smaller ISP but Mindspring access (or something similiar), tell the smaller company! They want your business...I used to be on a server that allowed me 30MB of diskspace for a website. How...I told them I wanted it and paid an extra $5/month for it. I live in a small town of 40,000 and could get it done...surely someone in a larger city with several ISP's available can do it.

Sounds like a wonderful idea...I wished someone would pursue it!

Also...consider making it a .gif. The image is a B/W and by reducing it down to B/W only, size will be very little...about 20K. 1024K/20K can get 50 schematics up and still have 24K for a text only webpage. Want fancier webpage, cut down a schematic or two.

"Loek d'Hont" <ldhont@ti.com> shared these priceless pearls of wisdom:
->I am restoring some radios but have problems with repairing the aluminum
->coating.

What you are looking at is the chromate version of Alodine. Alodine is an aluminum chemical film corrosion inhibitor and is really quite excellent. Most well-stocked automotive paint stores (not the handyman stores) have alodine.

I would suggest that you get a bottle of Metl-Prep while you are there. It is a alkaline etch for the aluminum that strips the old corroded aluminum surface down to the bare clean metal. THEN Alodine it and it is good for a long time. Watch out, the stuff will turn you into a girl if you spill it on the wrong spot.

Be VERY CAREFUL with the Alodine. There have been some credible reports that it is a decent carcinogen. Then again, the same is said of filet mignon.

If the paint stores don't have it, the aircraft parts houses certainly have it. We couldn't live without it in the flying game. By the way, if you have the option to use stainless steel hardware with the chassis, it will cut WAY down on that "powder white" corrosion that you see.

The low voltage markings on the ethernet thicknet coax is just to make
the fire inspectors happy, that serious power would not be piped thru
it when used in office buildings. That it could be strung thru the
ceiling without being enclosed in conduit. In ham use it can handle
whatever foamed RG8 can handle. Inspect it for vampire tap holes
though.

In reference to one of the amateur radar messages recently posted, I would like to get a copy of the Gunnplexer Cookbook article refering to chirp with a Gunnplexer. I have done some experimenting with FM-CW on the MACOM 87127 by modulating the varator with a triangle wave with a period of 10 hz and amplifying the audio tones from the mixer. Of course the higher the frequency the farther the object.

I think i would prefer to use a pulse radar, which is legal on all of the amateur microwave bands except for 23 cm and 3cm. Does anybody know why? I would like to correspond with anybody sharing a similar interests.

Somewhere on my shelves I have the Hamtronics VHF WEFAX receiver, IF board and audio. As I recall there is a P.S. built in along w/ an A/D converter I used to use with MultiFAX software. Xtaled for 137.5. Front panel has volume and squelch. Rear panel has antenna in, connector for lines to the computer. This is all nicely built in a Pac-ATec enclosure. Haven't used it in years. Also have a Spectrum Int'l 1.7 Gig to 137 downconveter. Let me know if you're interested and what you trhink is reasonable for the RX.

Source record: 101585
Cross-posted to: rec.radio.amateur.boatanchors,rec.antiques.radio+phono,rec.radio.amateur.homebrew

As per the usenews standard procedure, I posted the binary images in the binaries group: alt.binaries.pictures.misc and not in this non-binary group here. Images of an ordinary AM tube radio of the late 50's that I modified to use sub-mini vacuum tubes. Bear with my satisfaction on the success of this silly project. Anyway, I changed the IF amp tube's grid bias from ground to the AVC line (bias thru the 1st IF secondary, that is). So, that's what's different from 2 weeks ago.

Image of the radio insides with the sub-mini's in place, another image of the schematic of this radio.

This might have been the next generation of radio electronics, if transistors had not been developed.

Sub-mini tubes were small "pencil" sized tubes, about 1/3 inch diamenter and ranging from 3cm to 5 cm tall. Mostly found in military surplus "boatanchor" radios of more recent tube vintage. I could post some info on various tubes, I have a manual that includes some sub-mini's.

It's a major hazard, as far as our safety people are concerned, and I'm
frankly surprised it's available retail. Handle it with great care.

It does work well, though, which is why its corrosive and carcinogenic
properties are tolerated.

Message-ID: <199610222137.QAA20844@wymple.gs.net>
Source record: 101437

Hello all:

I'm looking for a U.S. source for the PC mount RF connectors used by ICOM and other manufacturers for inter-board coaxial connections. These are the jacks that are about .35" high, .15" shell inside diameter, center pin .06" diameter. Mounting tabs are .2" apart for the shell, with the center pin connection offset .1" between them (in a triangular shape). Material is silver plated. Insulator looks like nylon.

The mating plug crimps to RG-174 (in the Icom rigs it's grey cable).

Can anyone come up with the manufacturer and part number, maybe a distributor? Icom America stocks them in small quantities, but the folks there don't have a clue as to who makes them.

BTW, I need over a thousand of them. (sheesh...)

I'm looking for some schematics for LOWFER experimental band transmitters. So far I've found only one, and certain components in the design make it less than desirable for me to try. Specifically, I'm wanting to try to build it with surplus components and home-wound coils.

I've looked at several of the LOWFER-oriented WWW pages already.

If you've got something, please email me. If you've got a schematic and can digitize, please feel free to email attach. If not, email me and I'll send you a SASE. Thanks.

>The getter...in the metal anode 3-500Z. It's coated on the anode, and is only
>fully activated with some anode color.

You're absolutely correct, Tom. Reid was kind enough to get the drawings out and check for me. He says, " The 3-500Z uses only a [zirconium] coating on the anode for gettering in the 3-500Z. This works to some degree at anode temperatures as low as 300 degrees C, but better of course when the anode is red hot. There is no tab or other getter in the tube."

I doubt that the filament is getting the anode hot enough to be effective but I do not know that for sure. If it isn't doing a good job--as implied--then idling the filaments with no anode color would certainly be inappropriate.

Sub-mini tubes were small "pencil" sized tubes, about 1/3 inch diamenter
> and ranging from 3cm to 5 cm tall. Mostly found in military surplus
> "boatanchor" radios of more recent tube vintage. I could post some
> info on various tubes, I have a manual that includes some sub-mini's.

Well, in my day, early 60's they were being used as television antenna pre-amps
and called Nuvistors. That was almost the last hold out of tubes until those
silly-assed 5 functions in one tube compactrons came out. Fortunately those
only lasted a few years, since almost every one was proprietary.

2144. Re: opening ICOM battery pack BP84?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-22 00:00:00 UTC
From: poplawtm@ykt0.attnet.or.jp
Message-ID: <54ldef$2hl@ykt0.attnet.or.jp>
Source record: 101449

As I sit here reading your post I glanced down at what was one a Icom BP-84 pack I tried to take apart. I tried to pry the bottom off and managed to do so with only <minor> damage. It is glued all around by an unknown type of adhesive. Inside you'll find the batteries themselves easy to remove. The bottom was permanently deformed by the process and wouldn't look right. If I find a similiar sized piece of black plastic to glue back in its place I might try to put it back together again. I decided to get one of the cheap replacement packs sold in the back of Ham Magazines. If I had it to do again I would get a NIMH replacement with twice the capacity or the same capacity and half the size of the humongus BP-84 - and might try heating the bottom of the pack to try and loosen the adhesive.

Cheers,

If a message is ever rejected, please contact the list's owner:
listown@jackatak.theporch.com

For information on this service and how to use it, send the following request in the body of a mail message to listproc@theporch.com:

HELP

All requests should be addressed to listproc@theporch.com.

WELCOME TO THE BOATANCHORS MAILING LIST

We hate to say "welcome" with our hand stuck forward looking for money, but this is important for our survival as a useful resource.

TANSTAAFL (There Ain't No Such Thing As A Free Lunch):
The "boatanchors" list is privately funded and managed, which we feel gives more stability than a site dependent upon an individual's affiliation with an employer or university.

In the interest of keeping it this way, the members of the list have agreed among themselves to help defray the costs of its distribution through annual subscriptions, beginning 15 March 1996, with an annual fee of $12.00.

You will, as a new subscriber, have a "trial" subscription of about four to six weeks, which should give you plenty of time to look us over and make up your mind, as well as time to get your subscription in and processed.

If you find the information and fellowship here useful to you and you want to do your part to ensure the continuation of 'boatanchors'

you may send your subsription of $12.00 (be sure to include your email address on the check) to:

Jack G. F. Hill
P. O. Box 1685
Brentwood, TN 37024-1685

We can also take MASTERCARD, VISA, and AMEX -- FAX your card number and expiration date (with email address) to:
(615) 459-0038
The charge will be from "Delker ELectronics, Inc"

Now, with the business out of the way, on to more about the BoatAnchors mail list...

1. This mailing list is devoted to the discussion of vintage communications equipment, which we fondly refer to as "Boatanchors," and to closely related subjects. The central theme is vintage amateur radio equipment using vacuum tube (firebottle) technology, but we have been known to drift into discussions of such things as entertainment boatanchors, early tuned fgeeder antennas, telegraph keys, classic electronic/radio books and radio history.

** Note **
There are some topics that are too emotionally charged to generate worthwhile posts: in particular, the ARRL, Code versus No-Code, and the Examination Process, are all topics that can be discussed in other forums, and are considered inappropriate for this list. Please do not even *think* about posting about these subjects.

**** Special Note:
Even though we all prefer that there be few or no "rules" we have to have three hard and fast ones:

First, because, in the past, we have encountered problems with ARRL Bulletins being posted to the Boatanchors List, we must ask that you never post an ARRL Bulletin here, even if the subject matter is PRIMO Boatanchors.
Just do NOT do it.

Second, please do NOT ever "ping" the list... There is NO reason to send a test message to the list. If you are encountering delivery problems, please contact:

listown@jackatak.theporch.com

Due to the size of the list, even one or two "pings" result in a very heavy (and unnecessary) load on the list (especially if it is trying to recover from a crash.)

Third, do not discuss list policies on the list. There are other suitable forums available for such discussions, but never is the list an appropriate venue.

2. You will find the accumulated wisdom available here to be an invaluable resource if you have questions about vintage radio operation, maintenance, restoration, or history. If you have knowledge or expertise that can help answer a question, please post your responses. You may think that the answer to a specific question is best directed to the poster via direct e-mail. Sometimes, that is the best approach. But, some of the better threads on this list have been generated by a single question. So, when in doubt, post the response to the group.

3. As in most polite societies, we deplore the use of ANY electronic violence such as flames, personal attacks, and long-winded diatribes of any type. Please be courteous and polite. We think this mailing list has one of the highest signal-to-noise ratios on the InterNet and we want to keep it that way!

4. For sale notices and items wanted are welcome, IF the items are boatanchors and related equipment.

-- For long lists of items, direct them to:
listown@jackatak.theporch.com
so they may be made available to those who want them without burdening the entire list... And,

-- Please do ALL the haggling and negotiating via private e-mail or other means.

-- And, PLEASE do not post an advertisement for a commercial venture whether a newsletter, book, organization, or the like. We agreed long ago that these types of commercial uses of the list were at odds with the spirit and culture of the list. And please note that "commercial" has NOTHING to do with IRS status... it refers to organizations (and individuals) who habitually perform a service or sell something.

5. We ask that you limit the size of your responses, where possible. In particular, the list culture is different from many corporate environments, and the wholesale inclusion of a previously posted message is considered in bad taste when you use the reply function. Please edit the original posting to delete the parts that are not needed to understand your response. That effort will reduce bandwidth and storage requirements which, in turn, will make all subscribers much happier!

For long posts, such as a construction project, listing of military equipment contracts, and the like, please consider sending them to the list owner (listown@jackatak.theporch.com) so they can be posted to the list server for optional downloading, rather than posting a long post to the list as a whole.

6. This is the third incarnation of the Boatanchors mailing list. The original listowner was Jim Lockwood, KM6NK, who began the list at his workplace in August 1992 as a way to find other people who share his interest and passion for "heavy iron." When Jim moved East and

gave up his InterNet access, the reins were transferred to Paul Prescott, N1AAC, who ran the list for about 12 months through the good graces of MIT. In December 1994, "BoatAnchors" found a home on theporch.com with the current listowner, Jack GF Hill, W4PPT.

One of the more interesting things about this list is the fact that most of the original subscribers are still around.

7. The listowner is happy to provide this service via a list processor that supports subscribe, unsubscribe, and subscription delivery option changes and functions via correctly formatted messages. Problems that cannot be resolved by sending e-mail to the list processor should be addressed to:

listown@jackatak.theporch.com

Please *do not* submit such administrative messages to the whole list! Such messages only irritate the readers. If you remember only one thing from this message, remember that a "Help" message to the list processor (listproc@theporch.com) will get you instructions on how to unsubscribe or change your subscription options.

8. Hot Spare Boatanchors List

In order to reduce the affect of host outages at the main list server site such as we all experienced in Fall '94, a "hot spare" list server is set up at boatanchors@beacons.cts.com. It will normally be disabled, but in case of an outage at theporch.com a message will be sent to the list indicating the spare list address is to be used for list postings until the problem is resolved.

The subscription list will be mirrored at the spare site so that the disruption of list traffic will be minimal. The spare site will not be activated unless the outage persists for more than a day. In case of an extended outage of the main list site, subscribe/unsubscribe requests can be handled by the spare site since it runs the same software as the main site. Use the address listproc@beacons.cts.com, list name BOATANCHORS, for such requests.

9. This subscription is available in two formats. The first, also the default is to have each posting to the list mailed to you separately. If you want it like that, you don't have to do anything. The second option is to receive digests which means the messages are collected and mailed out to you only if it exceeds a length limit (approx. 1,000 lines or a time limit (one day). To change to the digest form, sent email to:

listproc@theporch.com

with the following body:

set boatanchors mail digest

If you want to temporarily suspend receiving the list but don't want to
sign off the list, you can set your mail to postpone by sending email
to listproc@theporch.com with the following in the body of the mail:

set boatanchors mail postpone

This will stay in effect until you change your mail status to one of:

ack noack or digest
(ack, the default, reflects your posting to the list back to you;
noack is individual messages, like 'ack' but does NOT send your
own submissions to you;
digest sends a daily compendium of messages, or when there are 1,000
lines of message)

10. Getting the FAQ

If you want to read the FAQ for the boatanchors mailing list please
send email to listproc@theporch.com with the following content:

get boatanchors FAQ

You will receive this via email in a short while.
Please note: the FAQ is about BoatAnchors, the gear, not about the mail list!

11. Again, welcome to Boatanchors!

The boatanchors newsgroup is called rec.radio.amateur.boatanchors - and you subscribe using your newsreader program. The information file that was posted refers to the Boatanchors-List, a fine-business mailing list that has been around since August 1992 and is an excellent resource on the subject. The two are not the same - one is a mail reflector and the other is a usenet newsgroup.

Plastic fiber won't pass UV light. In fact, it will be quickly
degraded by any UV light of useful intensity. A quartz fiber
might work. Any optics in the light path would have to be quartz
too. Finally, plotting would have to be (very) slow to adequately
expose the resist.

> the difference.

I recall these Continental rigs. The r.f. tube and the modulator tube were in Series for DC, and the voltage would split between them. The modulator, or switch, would vary the voltage on the tubes, at peak the full supply voltage would appear across the r.f. tube, at a valley, the r.f. tube was basically zero.

Also, as I recall, the thing was not very linear (not enough to pass the proof-of-performance FCC test, so Continental sampled the r.f., fed it back (negatively) to a correction amplifier or speech amplifier to distort the modulation in such a way that the resulting distortion was cancelled and a clean output would result.

This same thing was also with the old Doherty transmitters with quadrature-fed (r.f) tubes that were grid modulated and also acchieved high efficiency without transformers and modulation chokes. Westinghouse liked these, if I recall correctly.

Does anyone know where I can get schematics for VGA monitors? The company I consult for uses them on small boats and they get lots of pounding and vibration. I put 2 in the trash yesterday. I could repair them and give them away or save a few bucks. Also SMPS used in PC's (250 to 500 watts). Should be good for something in the shack! I have disposed of at least a dozen monitors in the past year. $250 $300 a pop adds up quick.

Hello All

I have a DX-40 Xmitter and VF-1 VFO .
Deake 2B Receiver
Problem.... I need a copy of the manual for the VFO.
Would really appreciate a copy of the
Heath construction manual.

It would be nice to have a copy of operators
manual for the Drake Receiver.

I want to be ready to start work on my old BA equioment
just as soon as I take the Gen. License Exam.

Thanks for your help.

You remember the theory well. But the series arrangement actually has three variants, one called classic, one called PWM, and one called PWM; Harris used PDM, Collins/Continental used PWM.

> the thing was not very linear (not enough to pass the proof-of-performance FCC test, so Continental sampled
>the r.f., fed it back (negatively) to a correction amplifier

That's entirely incorrect. Either one of the three systems is very linear. Harris did sample the RF and feed it back into the power control and audio circuits. Collins/Continental never did use RF feedback on any PWM rig--and there's lots of reasons why. Collins/Continental did use an advanced feed-forward error correction circuit that sampled, among other things, the total supply voltage. The input audio/DC-Reference signal was corrected for non-linearities in a four-quadrant Hilbert Multiplier stage.

>This same thing was also with the old Doherty transmitters with
>quadrature-fed (r.f) tubes that were grid modulated and also
>acchieved high efficiency without transformers and modulation
>chokes. Westinghouse liked these, if I recall correctly.

No. Western Electric was the big Doherty amplifier manufacturer before Continental Electronics came along; Westinghouse developed their own high-level plate modulated transmitter called the 50-HG. The grids of the Doherty were not modulated by CEC; that was Western Electric. We always used a screen modulated driver. Mr. Weldon, the founder of Continental Electronics, found a new way to drive the carrier tube (grounded-grid) that stabilized the input impedance and lowered the feedback requirement from 30db to 10 db.

I should add that feedback was used in almost all transmitters (except the Collins/Continental) to control the hum from the PA filament. For instance, on the 50 KW AM that Harris made, the noise was about -52 db and 99% of that was attributable to the PA and Driver filaments. They used RF feedback to control that hum. A side benefit (for them) was also to use the RF feedback to control a power drift problem that the early PDM rigs had.

Source record: 101532

Quadrature modulation, in simple terms, simply refers to the separation of the baseband signal into two components, like the Fourier transform sine and cosine series; mixing these two components up the RF frequency independently, and then re-combining them in a linear combiner (a simple summing circuit). The two baseband components are referred to as the I, for in-phase, and q, for quadrature phase, components. The LO signals that up-convert the baseband components to RF are equal in frequency but phase shifted 90 degrees. These circuits can theoretically be used for all modulation/demodulation techniques, but are very popular for various data communications such as pi/4 DQPSK. For AM and SSB, undergraduate communications textbooks will refer to synchronous detection. This is essentially a quadrature demodulator in disguise. Hope this helps

>expose the resist.

I wonder. I would assume that exposure is a function of
time * luminous flux/area. If I can expose a 3x5 board
in 10 seconds with a 60 watt sunlamp, that's 15 million
square mils. Now suppose I can concentrate that down to
a spot 50x50 mils, wouldn't that allow an exposure time
of 0.001667 second, or a plotting speed of 30 ips?

I'm not sure I could concentrate a 60 watt sunlamp down
that tightly without burning something up, but most of the
sunlamp's output isn't UV. If I used an 8 watt germicidal
lamp, it would probably put out more UV but lots less heat,
so things shouldn't melt too quickly if I concentrated that
down to a 50 mil spot. I could live with a 30 ips plotting
speed. Turn on and turn off delays would be a bigger problem.

That's right. Our Harris doppler weather radar runs a whopping
20 watts chirp, but gives us the same 250 mile coverage as our old
75 kW pulse radar. The major difference is the vast improvement
in receiver technology. Instead of a 1N21B diode detector in the
front end, the newer unit uses a GASFET preamp, coherent detection,
and DSP back end processing.

> Thanks for the help.

A quadrature modulator simply takes 2 signals and suppressed-carrier
modulates them onto 2 RF carriers that are 90 degrees out of phase
(sine and cosine). If the 2 baseband signals are 90 deg out of phase
with each other, you can get SSB at the output, either upper or lower
depending on how you combine the outputs of each modulator.

I've used the RF Micro-Devices RF2422 which is a part for the 1 GHz to
2.5 GHz range with internal quadrature carrier phasing. Works like a
champ within it's ratings and limitations. Quite a simplification from
the procedures of a decade ago. They have a web site with data sheets
and app notes - http://www.rfmd.com/

As the major manufacturers of oscilloscopes STOP the production of
analog scopes, digital alternatives are the rave. And when they show
up for $100 or less, its an opportunity one should examine carefully.

Since digital "sampling" can be accomplished in a variety of ways,
what gets presented isn't always what you might expect. "A little
knowlege is a dangerous thing."

My home page has a link to the latest "Digital Scope.FAQ" that
characterizes some of the concerns one might investigate PRIOR to
selecting a scope.

Thanks for reading this post. I recently received an used tv antenna from my brother-in-law. It's in good shape since it was in the attic. (no corrosion) The longest dipole is just a little shorter than is needed for the 6 meter band. I put some 8" extensions on each side of the dipole but have yet to cut them. My question is this:

What length should I cut the dipole to to get in the middle of the band? (52Mhz)

I have calculated it at 113.5 inches from tip to tip. (1/2 wavelength) should it be a little longer or shorter? Any help would be greatly appreciated. I'm building a qrp single chip 6 meter fm transmitter and would like to use this antenna. Thanks...

>but better of course when the anode is red hot. There is no tab or
>other getter in the tube.

And hence my point about some of the wild claims about parasitics and such.

There are two primary causes of arcing in the 3-500Z (assuming it was good at one time). You either have let the thing sit dead cold long enough for it to gas up, or you've never run the thing red enough to properly getter the tube.

The worse thing in the world for tubes like the 4-125, 3-400, 4-400, 3-500Z, 3-1000Z, 4-1000A, and others is to NEVER run them with some anode color.

When you turn em on, it won't be a little space Martian causing an avalanche of current, it'll be gas. The only way to de-gass em is to get the anode hot, and you can't do that without making em arc unless you pull the grids up positive and lower the HV.

: Bill Baka

The Nuvistors I have seen are metal tubes that were smaller than
the (glass) pencil tubes. The pencil tubes have leads that were
either all in a row, or all on the circumference of a circle;
the nuvistor pins were arranged differently.

Nuvistors are different from the pencil tubes (which are older). The
Nuvistor had a metal envelope and a form factor like a fat TO-5 transistor.
The pencil tubes have a glass envelope, and are tall and slender with wire
leads coming out one end. AFAIK Nuvistors were only offered as triodes,
with the 6CW4 being the most popular, but the pencil tubes came as tetrodes
and pentodes too (some with leads coming out both ends, some with contacts
which snapped into a holder like a fuse). The Nuvistor worked well at VHF,
but the pencil tubes didn't (too much lead inductance).

There were also planar tubes, some of which slightly resembled the pencil
tubes, except that they had a grid disc in the middle, and those did work
well at VHF and UHF. Other planar tubes, such as the gold plated WE416B,
looked more like a Nuvistor on steroids, though it had a grid ring and a
plate cap. These would work up into the low GHz. Other planar tubes were
called lighthouse tubes, and also worked up into the GHz. The metal/glass
2C39 is a popular example, since superceded by the metal/ceramic 3CX100A5
which is still used as a power amplifier tube at L band.

CAPMan - The recognized leader in HF propagation prediction software
using the
proven IONCAP engine. CAPMan is a mature package for amateur and
professional
alike featuring advanced system analysis.

CAPMan is excellent for system analysis, meaning in part that it
really shines for use in learning how a particular antenna will
work under real world conditions.

Good Luck,
Jim

>Where did I go wrong (and don't tell me it was buying RS in the first place).

The 2.2 k resistor forms the "leaky PTT" for the radio, and is configured
properly. The radio should be going into transmit with the circuit as shown
when you close the PTT switch.

If it is a dynamic element you're trying to use, the capacitor
needs to be in series with it rather than in shunt, and probably
should be a larger value as well. If you're trying to use an electret
element, the circuit should work as shown if the FET preamp is built
into the element, though I'd drop the shunt capacitor value to 0.001uF.
If the element doesn't have a built in preamp, you'll need to add one
to boost its output up enough to drive the radio. You need about
100 mV peak to peak to drive the radio to 5 kHz deviation. If your
mic element is putting out lots less than that, it won't do without
an added preamp.

Oh, I kinda liked the "Windows is a piece of $#!%" and "My watch boots in 100nSec" posts.

;^)

> c.) I haven't found a flea yet that you couldn't find 120VAC SOMEWHERE, If
> your spending more than a hundred dollars or so test it out before you buy.

Ah! If you are really serious about buying equipment, carry one of those little 200W 120VAC inverter bricks *with you* in your backpack, along with a cigarette socket to car battery clip adapter. Keep a small marine or gel-cell battery in your car (or with a friend who has a table).

This way, when you "roll up" on a good deal, ask the seller if you can borrow his cigarette lighter, or car battery, for a few minutes. If you can't use his car (and if you have time), run back and get your battery.

If he refuses...There's your answer!

I keep an 8-cell "AA" battery holder and an assortment of pigtail power connectors in my backpack. This way, I have an adjustable 1.5 to 12V power source to test things there on the spot (I'm planning on making a complete test box, complete with ammeter and current limiting).

I also carry a bunch of "AAA" and "C" cells in my backpack ("C" cells can be shimmed into "D" holders with a few coins between the batteries).

The same rule applies, If they won't let you test it.....etc,etc,etc.

Will they give you their business card or phone number? Make it clear you will not bother them unless absolutely necessary (secretly write down their license plate number, for "Justin Case").

Also carry a pocket DMM (This is a *must* for any flea enthusiast - NEVER buy batteries w/o testing them first!) and a small, bright flashlight (for "inspections").

Smell the equipment too! This can be a big clue as to it's condition. Does it smell like something blew up? Does it smell musty or moldy?

Another clue I have found is the physical condition of the unit. Sometimes the "cleanest" unit of the bunch is the one that failed prematurely and got stuffed on a shelf or back in the box. Whereas the "used looking" units were just taken

out of service.

More importantly than "functional", is "complete".

Nuthin' worse than getting something and finding out a piece, or a board, or a module, or an expensive or rare IC is missing. Now you know it's not functional, and there may be little chance of it even becoming functional again.

I always assume "dead" until happily proven otherwise. Follow your instincts! If you have doubts, there's a reason! I always concider the scrap value of the item also. Any expensive goodies in it? The power switch may be worth more than the item!

Some of my best deals were the "I don't know if it works...Oh,..five bucks" deals.

It's a gamble...Ya' win some, ya' loose some!

Caveat Emptor!!!!! <sp?>

(Let duh buyer beware!)

Which recieving tubes can be used for transmitting also?
I've done it with a 6L6WGB, a 1U4 & a 3A5.
Which tubes make good RF amplifiers? I'm not expecting a lot of power maybe 50 watts max. I've heard some sweep tubes can do up to maybe 200W in CW or SSB service. I remember seeing a magazine article using a pair of 50C5's. Also heard of using 45 tubes but not sure what they would put out.

Hello,

I'm looking for a simple circuit that can be built to generate modulated CW tones
for an FM transceiver and also has a PTT delay feature that would allow the use
of a straight key or keyer/paddle combo to send MCW in semi-break in style.

We are attempting to get more new HAMs involved in CW and presently they need
to pass a 5 wpm before they can even practice on the air. If only someone made
cheap VHF QRP CW rigs or kits like everybody and his brother does for HF.

Thanks for your replies.

Gary Coffman (gary@ke4zv.atl.ga.us) wrote:

some things about exposing a photoresist coated board with a plotter
driven light source.

FWIW, I've had good success laser printing to a sheet of tracing paper
which I then use as a transparency to expose a board coated with
Shipley AZ111S photoresist (probably same as the GC positive stuff;
GC probably just repackages the Shipley). With a 300dpi laser printer,
I can do 8 mil lines/8 mil spaces, though given a choice I'll not go
smaller than 10 mil/10 mil; a 600dpi could perhaps do 5 mil/5mil.
This is a whole lot easier for me than mucking about trying to get a
light source in the pen holder of my HP7220 flatbed. But there are
folk who swear by plotting directly to a bare board with the correct
pen/ink combination. I don't think they claim 5mil/5mil or even
reliable 8mil/8mil though.

It may be that an inkjet printer can put down dense enough ink on a
transparency to be used for board exposure, but I've not played with
that. But I do know that it's darn hard to get good enough density
on a laser-printed transparency. The tracing paper thing works much
better for me. You can get the laser printer to handle the thin paper
by folding a leading edge over a thicker piece of paper (e.g., 20 pound
stock).

For anything where dimensions are really important, it's hard to
equal a photoplotted transparency. It's worth getting one made for
critical things, IMO.

Because the folks here don't want you to know WHERE Ten Tech is:
Here is a toll free phone number for you:

1-800-833-7373

If you want a pretty nice regenerative receiver kit for Ham bands,
look at the model 1253, at $59 bucks. It is in a very nice metal
cabinet, and works very well. While it does not have the sensitivity
of some high dollar scanners, you can hear around the world with it,
none the less.

No, I don't work for TT, but I like their stuff, and it IS made in the
US.

BTW: Their 2m/6m and other transceiver kits are getting an UPGRADE! I
wanted to get the processor source, and modify the unit to be able to
scan. You will be able to upgrade your TT kits for SCANNING ability! I
talked with an engineer today, asked for the processor software
source, was declined, but was assured that they are working on a
scanning capable upgrade! Really good of them, I thought!

Have fun.

> >> and ranging from 3cm to 5 cm tall.

Subminis came mainly in three sizes:

T3 (tubular, 3/8" diameter)
T2 (tubular, 2/8" diameter)
T2x3 (tubular flattened, 3/8" x 2/8", mostly Raytheon originated types)

> AFAIK Nuvistors were only offered as triodes,
> with the 6CW4 being the most popular,

Note that the nuvistor types 7587 and 8380 are both tetrodes.

I'm trying to gather a set of nuvistors, and I am looking for types:
8058, 8203, 8227, 8382, 8393, 8441, 8456, 8627, 8627A, 8628, and 8808.

Reply via Email if you have extras to trade. Condition is unimportant,
except they must display well.

Hi.

I have a friend who swears up and down that the length of the coaxial cable to maintain resonance at a given frequency is important for reducing the SWR. He feels that it acts in a similar principal to the fact that the elements of an antenna must be cut to the correct length for the antenna to be resonant at a given frequency.

It seems to me I have also read somewhere that this is a myth. I need the true scoop on this. I'm preparing to put up a pretty good antenna system on my roof (a homebrew 10 meter antenna cut to exactly the middle of the band), and don't want to purchase an extra 6 ft of Belden 9913 coax only to have it looped up and losing signal, when in reality I could of used 20 feet instead of 26 feet of cable.

Please carbon copy any responses to this post to jpoll@redrose.net so I don't miss any good info.

Thanks

Jim

Ok, this can get complex because there are several interrelated
things happening here. Lets take them one at a time.

The only thing that determines SWR on a transmission line is
the ratio of the characteristic impedance of the line to the
impedance presented by *the load*. Nothing you can do at the
generator end can affect SWR, and changing the length of the
cable won't change SWR either (but see below).

However, changing the length of the line will change the impedance
presented to the generator. That's because a transmission line with
any SWR other than 1:1 acts as a transmission line transformer. By
changing the length of the line, you get an effect similar to, but
not quite the same as, changing the turns ratio of a transformer.
The SWR doesn't change, but the impedance presented to the generator
does. This can be useful, and is employed frequently for impedance
matching purposes. The most common such is the quarter wave matching
section.

In general, the impedance transformation will be complex, IE it will
be in the form of R+jX, where X can be capacitive or inductive depending
on cable length. The Smith Chart can be used to determine the transformation
effect by following the constant SWR circle around the chart for different
cable lengths (measured in wavelengths at the frequency of interest) and
reading out the R and X values. Note that the SWR is constant, but the
impedance presented to the generator changes with varying cable length.

Now something else can happen too, and this is where some of the
myths have arisen. If you feed a balanced antenna, such as a dipole,
with an unbalanced transmission line, such as coax, the *outside* of
the outer conductor of the transmission line can become part of one

arm of the dipole, and antenna currents can flow down the outside
of the transmission line.

Picture the dipole as a 1/4-wave section connected to the coax inner
and an L shaped element consisting of the other arm of the dipole and
the *outside* of the coax outer conductor. This can change the *load
impedance* presented to the transmission line because the antenna geometry
has been altered from a physically balanced dipole configuration, and
thus can change the SWR. Changing the coax length changes the effective
length of one leg of the dipole, and that changes the impedance presented
at the load end of the coax, and that changes SWR in the coax.

Coax transmission line currents flow on the outside of the inner
conductor and the inside of the outer conductor. This is because
of skin effect. The physics of coax forces the currents to be
equal in magnitude and opposite in direction. The opposite currents
cancel any radiation fields, and the coax doesn't radiate. But that
doesn't affect currents flowing on the outside of the outer conductor.
Those currents are independent of what's happening inside the coax.
Their radiation fields aren't canceled, and the coax becomes a radiating
part of the antenna.

Generally, it is undesirable to have antenna currents flowing on
the outside of the coax because it will alter the radiation pattern
of the antenna, alter its feedpoint impedance, and because it can
cause "hot shack" problems in some cases. The cure is to use a choke
balun at the antenna feedpoint to decouple the outside of the coax
from the antenna element to which the inside of the outer conductor
is connected. (A choke balun can be simply a few turns of the coax
tightly coiled just before connection to the feedpoint. Or it can
consist of a number of ferrite beads slipped over the coax near
the feedpoint. Its purpose is to act as a high impedance to currents
trying to flow down the *outside* of the coax outer conductor.)

When you use such a balun, or if you are feeding an inherently
unbalanced antenna such as a groundplane mounted vertical, then
the coax doesn't become part of the antenna, so it can't change
the load impedance presented to the coax, and thus can't change
SWR. Any length coax can now be used without affecting SWR, or
antenna radiation pattern.

So you can see, there is some truth to the myth that coax length
can alter SWR, but it isn't quite the way many amateurs picture
it. The reason it can happen is because the coax has become an
unintended part of the antenna due to a failure to properly deal
with the unbalanced to balanced connection at the antenna feedpoint
with a balun.

2205. Re: Wanted Radio Receiver kit

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-24 00:00:00 UTC
From: psoper@encore.com
Message-ID: <DzsD99.3A@encore.com>
Source record: 101392

I bought a Ten Tech "any band" direct conversion receiver
kit and built it for 40 meters. It was straight forward to
build and works pretty well for something that cost $30-something.
Drift before warmup is significant and the RF gain has to be
used carefully where strong signals might be present. I put the
biggest knobs I could find on the tuning controls and getting
SSB signals tuned properly is still very very touchy. Overall
I'm very satisfied as it provides a prospective new Ham
with exactly what she needs for CW practice at this stage.

>but the pencil tubes didn't (too much lead inductance).

There was a tetrode Nuvistor, the 7587. The plate connection comes out
as the top half the the body--there is a ceramic spacer between the
upper and lower half of the body.

The Nuvistor has construction different from other tubes. The active elements
are cantilevered off of the ceramic base. There are concentric rings of
pins in the ceramic base, three pins per ring. A cone-shaped element
support is welded to the group of three pins proper to the element. The
other end of the cone ends up at the necessary diameter for the cathode,
grid, or plate. On the outside of the base, two of the three pins are
then cut off. The stubs are still there, and do make electrical connection.

The heater connections are not located on a ring--there are just two
pins in the center of the rings.

The cantilever construction does make the Nuvistor rather microphonic.

>
>Maroof

Ok, quadrature means a 90 degree phase shift, IE signals which are orthogonal to each other. These signals are called I and Q where I in the in-phase signal and Q is the quadrature-phased, or 90 degree shifted, signal.

Now there are various usages of quadrature in modulation and demodulation.

The FM quadrature detector is a special form of frequency discriminator. It splits the received signal into two components. The I signal is fed directly to one input of an exclusive OR gate (also known as a phase detector). The Q signal is first delayed 90 degrees by a LCR circuit and then fed to the other input of the XOR gate. The LCR circuit will only yield a 90 degree delay at the carrier frequency. At a higher or lower frequency, it will deliver a greater or lesser delay.

When receiving an unmodulated carrier, the lowpass filtered output of the XOR gate will be a DC level midway between the + and - supply voltages. If the signal is modulated, as the frequency swings higher, the filtered output of the XOR swings lower, and when the frequency swings lower, the filtered output of the XOR swings higher in proportion to the frequency change. That's because the signals slide in time with respect to each other according to the departure from quadrature of the LCR circuit at the instantaneous frequency. This recovers the audio modulation impressed on the FM carrier at the transmitter.

A different usage of quadrature allows generation or demodulation of amplitude modulated signals such as SSB. In this case, two quadrature delays are used, one at carrier frequency and the other at modulation frequency. Through use of a pair of balanced mixers and a combiner, SSB of either LSB or USB can be generated or detected.

Generically, the amplitude response of a quadrature system is

y = |sqrt(I^2 + Q^2)|

The phase response of a quadrature system is

phi = arctan(Q/I)

By combining the amplitude and phase relations with suitable
circuitry, IE multipliers, summers, etc, any arbitrary signal
form can be generated or detected since any signal modulation
can be described in terms of its instantaneous amplitude and
phase.

The length of coax doesn't change the VSWR, assuming it's all the same impedance. However, the impedance at the transmitter output will be a function of cable length if the VSWR is not 1:1. Ultimately what matters is not the VSWR, but the impedance match to the transmitter. All that is required is a conjugate match so that the transmitter sees a resistive load of the right resistance at the output device.

There is one way that the coax length affects VSWT. If the attenuation is high the VSWR gets better with length. Someone once said a good low power load for 144 MHz is 100 ft of RG-58. It doesn't matter too much what's on the far end.

Hi Viny, I'm trying the same thing but only Doppler Speed so far on
10ghz. Ended up on 10ghz ssb/cw and hilltopping but think the radar
aspect could be done with 1mhz or 10mhz square wave or triangle
and measuring phase delay on those modulated sigs right from mixer
out to sampler/detector. 1 mhz would give 150m distance and
10mhz would be good for 15 meters away. Wd make neat low cost
Altimeter for Aircraft on ILS or Helicopter??
Will look for your messages on here.. 73 de Dave Riley AA1A

Sounds like a job for a dual 555 timer chip. Run one section astable as your tone generator, and run the other as a retriggerable monostable with a time constant set for the hang time you want. The first section feeds the FM rig's audio input and the second feeds its PTT. Key closure gates the astable tone, and starts the monostable.

>We are attempting to get more new HAMs involved in CW and presently they
>need
>to pass a 5 wpm before they can even practice on the air. If only
>someone made
>cheap VHF QRP CW rigs or kits like everybody and his brother does for HF.

Sounds like a club project. Some of the FM receiver on a chip chips have a RSSI output. The Moto MC13135 does, and it has a frequency response out to 80 kHz. That'll recover the keying waveform of a CW transmitter. Just let it drive a 555 astable to create a regenerated tone to be copied, or feed it to a microprocessor for automatic code reception.

The transmitter can be any keyed RF source. The MC2800 will do, or you can use traditional discrete osc -> multiplier -> PA style construction for the transmitter. A hand key or a microprocessor can generate the keying waveform.

Crystal control is best for simplicity of netting the units.

An alternative is a simple transverter, such as the Hamtronics kit, used in front of any of the 10m QRP rigs. After they pass the 5 WPM, they can use the 10m QRP rig directly too.

Or, you can use the R2 and T2 (kits available from Kanga), and supply a LO yourself. They're good up to 500 MHz depending on the LO you choose. These beauties can also be used on HF after the code test is out of the way, and they'll do SSB, FSK, or PSK too, IE they're I/Q radios and can handle any arbitrary

modulation form you wish.

You've got plenty of choices. You don't have to stick with FM MCW,
though that is simple if you already have FM transceivers, and that'll
let you use repeaters for range extension too.

Ah, there's the little matter of different sweep rates. But you're
right, we could have gone directly from B&W to PAL-M, which does
use the standard (to the US) sweep rates. Of course NTSC pre-dates
PAL and SECAM, so those weren't really options at the time. The
choices were NTSC or the CBS sequential color system (it wasn't
compatible either, but made much better pictures).

As a chuckle, here are some definitions for the acronyms.

NTSC Never Twice the Same Color
SECAM System Essentially Contrary to the American Mind
PAL Perfection At Last

In general, the correct length of coax for an HF antenna is the
distance it takes to get from the transmitter to the antenna. Don't
worry about length.

Quadrature modulation *is* the phasing method, or more precisely, the
phasing method is one subset form of generic quadrature modulation.
The Weaver method is something a bit different.

It's possible to use a cable with an impedance not equal to the characteristic impedance of your antenna and rig. For example, a half wave length of 75 ohm cable will work between a 50 ohm antenna and a 50 ohm transmitter. You can also use 75 ohm cable to match a 100 ohm antenna to a 50 ohm rig by cutting it to the right length. Unfortunately, these tricks generally only work at one frequency.

In this case, the length of the cable is critical to a given frequency.

Hi Jim. This is true if the feedline impedance is different than that of the antenna/transmitter. If you use 50 ohm feedline with a 50 ohm antenna/transmitter, any length is acceptable. If you substituted say, 75 ohm feedline, you would need to cut the feedline in 1/2 wl multiples (the impedance is repeated every 1/2 wl).

Heeelllp I need to create a changeover contact in a extremely magnetic environment. Relays are no good so I am looking for a manufacturer of something like, a bi-metallic switch that can be operated from afar with a built in heating element,ala car indicator flasher. Or maybe a mercury thermometer principle switch that closes a contact as it is internally heated. I know the latter exists but where can I get them.
Thinking caps on chaps all suggestions greatfully accepted.
Thanks Dave.

>what's on the far end.

There's one more way that cable length can affect VSWR. If common-mode current is present (that is, current is flowing on the outside of coax, or the currents in twinlead aren't equal and opposite), the feedline becomes part of the antenna. In that situation, changing the length of the feedline changes the antenna itself, which will affect VSWR.

VSWR can seem to change with cable length if the characteristic impedance of the VSWR meter isn't the same as that of the cable. I've measured RG-58 at over 60 ohms Z0, and a couple of cheap SWR meters I've looked at were off also, so I imagine this is a fairly common occurrence. In this case, the SWR doesn't really change with feedline length, but the SWR meter says it does.

>speed. Turn on and turn off delays would be a bigger problem.

You might try leaving the lamp on and using some kind of shutter. That would probably save wear and tear on the lamp, too.

I think focusing the spot down to size might be the bigger problem. Ordinary crown or flint glass lenses will pass UV down to about 330 nm or so. But different wavelengths will focus at slightly different distances. Even with monochromatic UV it may take some trial and error to get the focus right, if you can't see it.

And 50 mil is a fairly big spot. For my purposes I would prefer 12 mil, if possible.

Maybe you could focus down as tight as possible, then shine that through a small (10-50 mil) apperture close to the resist. Hmmmm....

I've used a 300 dpi laser printer on transparency film. Never tried tracing paper. I tried toner transfer, but it's lousy for spacing smaller than 25 mil.

Yes, the transparency density is marginal, especially on large copper areas.

But my wife recently bought a color inkjet printer for her business, and I'm in heaven. It's a 720 dpi Canon BJC-620 and it works *much* better than the laser printer. The ink density on transparency is substantially better than the laser printer's toner. And the 720 dpi resolution is real sweet.

I haven't tried any other inkjet printers, but I'm very happy with this one.

But you must be sure to use the special transparency material made for inkjet printers. I tried a sheet of laser printer transparency film in the inkjet printer and the ink clumped up in many places and ran in other places.

I don't have the cellular mod for the BC8500XLT but I have recently found an old newsgroup message from someone name Jon who claims to have a mod to enter out of band frequencies on the 8500 between 25 to 1300 MHz including the blocked out 800 MHz parts. He claims to have already modified two BC8500XLT scanners. The message only talks about the mod but does not include it.

I don't have this person's e-mail address but he goes on to say that he will be contacting Popular Communications to see if they will mention it in an up comming issue.

What I would like to see if someone has all the Popular Communications between 1993 to 1996 and check in several places that it might be, like the scanner column or letters area. Assuming that he contacted them and they published it.

If someone does find it, knows of a similar mod or knows of this person please E-mail me.

Hi Joel, got to nitpick a tad.

1. 100ft of RG-58 on 440MHz with an SWR of 1:1 and *no feedline radiation*
does make a difference.

2. 100ft of RG-58 on 28MHz with an SWR of 20:1 and *no feedline radiation*
does make a difference.

The Heath DX-20 (my first rig) used a single 6DQ6 TV sweep tube at 50 Watts (500 V x 100 mA). Other rigs have used two or more in parallel. I tried using a 50C5 as an rf output tube once, and could't get the darned thing to load, although I had used many other audio output tubes in a similar fashion.

It all depends upon the upper frequency limit of the tube (inter element distances, etc...)

Sweep tubes have an upper range higher than audio tubes because of the need to handle the sharp waveform of the horizontal sweep. IIRC the Drake TR-4 (I'll look in my garage) uses sweep tubes and is good up to 30 MHz.

I suspect that audio tubes (6L6 and friends) peter out at a bit lower frequency. On the other hand, RF tubes make VERY good audio tubes. I know of one person who used 807's in an audio setup for his "high quality" amplifier. Later (this was about 20 years ago) he went down to Radio Shack and got one of their "off the shelf" receivers and it was better (or equal to) his older setup. It also dissapated MUCH less power.

As always, YMMV.

Well,
Let's if I can do this reply. Yes, It's a myth! The only thing that's changing is the APPARENT XL-XC that the METER is seeing. We all know that the Electrical wavelength recurrs at a different distance than the phusical wavelength. The old velocity factor trick affects that (cheaper coax = lower VF). So, the loss is cumulative to the length, the SWR associated with the coax = myth.

If you want to play with the numbers of length, coax type, swr, ant gain, and effective power. Download TEEREV.ZIP from the ARRL BBS, or it's on the latest level of the QRZ CD-ROM.

Jim WD9AHF

P.S. I agree with the guy who said the correct length is what reaches! Just make sure that you look at what it costs. I wrote that TEEREV program to see what the tradeoff was between good coax vs an amplifier. You will be surprised at what the cost of 'cheap' coax is.

Jim
If the coax is matched (ie the load presents a resistive, 50 Ohm
impedance) then the length of the coax is unimportant, except that it
has loss depending on how good it is and the operating frequency. If
the load is not matched properly then there will be different
impedances at different points aliong the coax and you will get a
different SWR with a 50 ohm source, depending on where you feed the
coax. So your friend is correct if the load is not m,atched
accurately.

Aren't there enough contests already? Besides, you would get a lot of
replies from Switzerland. HI. But I support the idea of a meeting place,
a worldwide recognized frequeny on each band for homebrewers with their
equipment (all HB of course, kits won't count) on the air.

Look in the ARRL handbook. You will see tuners which are a pi network
or a T network. I have build both from junque-box components
purchased at a hamfest. Within certain limits, component values are
not critical. I have built using brass nails as solder points on a
pine board, and they work just fine. Be careful when running 100
watts adn up for RF voltages, but get after it...experiment. Your
chances of success are good....

Used to be a lot of equipment put together with TV sweep tubes as
power amps. My old Swan 350 had 2 6HF5's in push-pull and put our 350
watts PEP. There was a commercial linear amp using four sweep tubes
for a KW input, if I remember correctly. they do require a bit of
care in tuning as they do not brook much mismatch.

Basically, just about any amplifier tube can be used to do SOMETHING
as a transmitter at RF. It's just that some make better sense than
others.

Good point, Gary. I hadn't thought of that, but it makes a lot of
sense. Most of the systems I deal with have a resonant cavity load fed
with rigid coax where there is no chance of any rf currents on the
outside. (A good thing too, at 250 kW peak and 425 MHz.)

The ONLY time coax length makes a difference is when it is radiating
rf,thus it becomes an active part of the antenna,instead of the passive
conduit it is designed to be.

Sometimes we spend way too much time performing analysis on a problem rather than using common sense. I've been a licensed amateur radio operator for over 30 years and have worked in commercial broadcasting and two-way radio for almost as long. The correct length of coax cable IS "the distance it takes to get from the transmitter to the antenna."

While others will argue the technical merits or matching this an that, in the "real-world" it makes very little difference.

Oh well, sit back and wait for all the techno-wizards to dispute this discussion but I know what works and it works in 99% of the cases involved.....

> <again snippety>

Jim, in addition to the responses you've already received I want to add the certainty that even with RG-58 the "26 feet of cable" would result in essentially NO extra noticeable loss than "20 feet of cable". And with Belden 9913 the additional loss would be even more miniscule. According to my charts, the losses of these cables are: (per 100 feet @ 30 MHZ)
RG-58 2.5 dB
Belden 9913 0.75 dB (!)
RG-8 1.0 dB

So, even if you were using the dreaded RG58 the loss would be less than a fraction of a dB for the additional 6 feet or so of coax. Even with a high SWR (where the reflections cause more than one trip "up and down the coax" and thus increase the effective loss) 26 feet is not a big deal at all. 3 dB is generally regarded as a barely discernable difference on the receiving end without accurate test equipment to "help" notice the difference.
As your previous respondees have noted, if the SWR is high you CAN "fool" the transmitter into "seeing" a lower SWR by messing with coax length but far more will be gained by trying to lower the SWR up at the antenna FEEDPOINT which will not only make your transmitter happier but increase apparent antenna effectiveness too, both transmit and receive. "SWR" is SO overhyped as important anyway. I fondly recall in the '70's working all kinds of DX on 10 meters with a homebrew 2 (TWO!) meter J pole since I was a poor college student and didn't have the nerve to sneak HF wires onto the roof of my college housing.....
I suppose it worked so well because I didn't own an SWR meter, just heard the band was open and tried the J pole since that was all I had on the roof and had a blast with it, who knows what the SWR was, but I'd have had to QRT had I had a meter to scare myself with.....

>AL-80 with it's "state of the art "QSK" circuit?
>73, Jesse, W6KKT
>
>

Actually no, the responsible party was Denny Had of Dentron fame. While Denny is a very nice guy, RF was not his area of expertise. The QSK in the original AL-80 was a copy of Heathkits TR circuit in a two meter amp that used 1/4 wl lines and a conventional diode. He saw the circuit, never understood the theory, and stuck it in a HF amp.

Prime Instruments partially financed Denny to a new start (via parts and tooling purchases) after Dentron went bust. I was hired to help Prime produce amplifiers when the deal started to unravel. I ordered all the original AL-80's recalled and rebuilt at Primes expense, the owner of Prime, W8IOB, agreed. W8IOB is a wonderful guy, and very honest.

The AL-80 parts were run out until the AL80A was designed and produced, I sold the kit rights to Heathkit, whom I also did consulting RF engineering for. Heathkit changed the inrush, transformer and switch (leaving a corona ring off) against my wishes.

So, that grouchy 70-some year young Kurt (who really isn't so bad when you get to know him, even if he is "always right") had nothing to do with that PA. It was a much more pleasant guy, Denny, with good intentions but who unfortunately was not a "real" engineer.

In line with that thought, I'm not saying ALL the ideas on the Web page you mentioned are wrong, but some are *very* bad from an engineering concept. Many of the well intentioned suggestions will actually cause more problems than they will correct. I'm sure the intentions are good, even if the suggestions are not.

If I were you to point you to one reliable source, it would be Eimac's Care and Feeding of Power Grid Tubes or other commercial engineering texts. In commercial books, you have the benefit of people working in a team, double checking each other. You are less likely to hear rumor or folklore.

I'd be happy to discuss anything on the Web page one point at a time. You'll find I can give good reason for anything I say (that can be verified), rather than blaming disagreements on "coverups or conspiracies".

Lbliao,

1. It depends upon what you define as a 'transistor'. There are darlington transistors (two transistors in cascade) within a standard TO-220, TO-126 or even a TO-92 package which have current gains (Beta) of 1500-5000+. Most conventional BJT's have a Beta below 800.

2. It depends upon the application of the transistor. What are you defining as 'gain'? I assume you mean Beta. A given transistor has a different AC current gain to its DC current gain. For example, a transistor with a DC Beta of 100, will not have this gain when used as an (AC) amplifier.

These are just my opinions.

I missed the beginning of this thread, so I hope I'm on track. If you are trying to repair a surface that was black anodized, on alulminum, of course, I purhase a little bottle from gun stores, made for blacking aluminum, called "aluminum black". You degrease the surface, and apply sequencial amounts, with a cotton swap, etc. After a few minutes, the surface turns to a dull black. Not as good as anodizing, but at least you can do it at home.

I think the manufacturer is "Birchwood Casey". You might also try some sporting goods supplys.

I'm looking for some information on some ideas for a 2 meter
antenna. My call is N3XZX. I basically recieved a homebrewed antenna from a
gentleman in Atlantic City. I liked the idea and tend to build a few
myself. It's just a plain old ground plain antenna, The one i recieved was
a quarter wave and i was wondering if there was any ideas and info for
making the same type but creating a 5/8 wave.
I heard for a 5/8 you need to have a top hat, is this true? Also any
info on whether this 5/8 is a good antenna comparing it to the quarter wave.
Any info would be greatly appreciated!
Thanks,
N3XZX
(Chris)

Please carbon copy responses to x32-viper_ck@juno.com so I don't miss
any good info

>loaded Q, the tank losses are of little consequence. On the other hand
>it may be redundant to use resistive leads and inductors and a shunt
>resistor.

More than redundant, it's poor engineering. Here's why.

In a proper design the VHF path is primarily through the resistor, not the suppressor's inductor. The inductor completes the HF signal path, not the resistor. The best design would place the entire VHF path through the dissipating resistor, and NONE of the desired HF energy through lossy resistances.

This is especially a problem on ten and fifteen meters, where the output capacitance of the tube is the majority of the input capacitance of the tank. Using a lossy coil and leads now places unnecessary resistance in the HF tank, de-Qing the tank at the operating frequency. This reduces harmonic suppression as well as efficiency, and for no good cause at all if the goal is suppression of VHF signals.

The correct approach is to design the circuit correctly in the first place, rather than shotgun it with unnecessary losses that hurt desired performance while not doing a thing for the undesired traits.

Why de-Q the HF path that doesn't affect VHF stability, when the primary VHF path can very easily be made lossy with affecting the HF path?

> I also remember seeing something about film resistors. I
>guess I would prefer carbon composition or Carborundum resistors
>myself.

Myself also. If you cut open the film resistors that come with the nichrome suppression kit, you will see the resistor element is wound in a spiral around a ceramic form. This is the last thing you want in a non-resonant VHF suppressor, because it adds series non-dissipative inductance in the resistor path and forces the resistor OUT of the circuit at higher frequencies, right where it is needed most. What a PA really needs are the types of resistors you mentioned, carbon compositions or Carborundum type non-inductive resistors.

Why go through the bother of changing parts just to stick the wrong type components in? I don't call that an improvement or good advice.

For AC signals a single transistor of any type can be configured to have infinite gain...an oscillator is a good example.

Ahhh...that's the power of positive feedback!

In practice, a gain of more than 20, from DC to 100Mhz, and having superb operating point stability, all in a single stage, is a satisfactory accomplishment.

>does make a difference.

Your right, I'd much rather have 75 ohm 1" hardline WITH VSWR than 50
ohm RG-58 at 450 Mhz.

>2. 100ft of RG-58 on 28MHz with an SWR of 20:1 and *no feedline radiation*
>does make a difference.

Again I'd rather have 75 ohm cable TV hardline .5" than RG-58.
Cecil is right, the general rule is get what you can for the lowest
loss. Hgh VSWR adds a LOT of loss to an already losssy cable.

I didn't wade through all the material, but I don't see anything
fundamentally wrong with de-Qing the tank circuit VHF resonances.
After all that's what the parasitic choke is doing. As long as the
tank circuit fundamental resonance unloaded Q is high compared to the
loaded Q, the tank losses are of little consequence. On the other hand
it may be redundant to use resistive leads and inductors and a shunt
resistor. I also remember seeing something about film resistors. I
guess I would prefer carbon composition or Carborundum resistors

I have seen some devices (VCRs, for example) that also use the 60 Hz as a
reference clock for some circuits. When I adapted a JVC VCR to 12 volt
operation I had to use a CMOS chip that used a color burst crystal to
generate
a 60 Hz square wave.

Check for other voltages, as mentioned, also.

Try disconnecting temporarily the 12 volt power supply and run the 12 volt
circuits
from a battery, while the unit is still plugged in. This will verify that
the 12 volt
input is within range for the circuits, and also would prove that there is
either a
clock or power path from the power supply that you missed...

PS, fuse and zener protect the input!

ARRL currently has a program under development which analyzes transmission line. I'm fortunate to have been asked to play with an early copy. Running some quick examples shows the following:

At 28 MHz an antenna with a purely resistive load of 50 ohms fed with 100 feet of RG213 has a loss of 1.181 dB. There is no additional loss due to SWR.

The same antenna fed with 100 feed of 1/2 inch 75 ohm hard line has a loss of .420 dB due to the cable and an additional .032 dB due to the SWR for a total loss of .452 dB.

An antenna with a purely resistive load of 500 ohms (10/1 SWR) fed with RG213 has a loss of 1.181 due to the cable and an additional 2.702 dB due to the SWR for a total loss of 3.883 dB.

The same antenna fed with 1/2 inch 75 ohm hard line has a loss of .420 DB due to the cable and an additional .032 dB due to SWR for a total loss of 452 dB.

Incidentally, I chose purely resistive loads just to simplify things. The program works with complex loads as well. If anyone would like a specific calculation you can eMail me. All that is needed is the type cable, the length of the cable, the frequency and the load, (resistive and inductive).

Regards, Merv

The power gain of a Class A common emitter MOSFET is infinite in
theory. In practice there may be some leakage current in the gate
which makes the power gain less than infinite. For AC signals, the
gate capacitance charge/discharge characteristic means some finite
amount of driving power is required, so power gain is not infinite.
Still, it is possible to achieve very large power gains with small
signal Class A amplifiers.

Tom, almost all of us are insane to put up with soldering these very small connectors. Unless you can find a tip that is small enough to fit an existing soldering iron, the next best solution is simply to wrap copper wire of small diameter around your existing iron. The last turn is extended forward far enough to solder but not block your view. A chisel tip can be formed by simply your cutters and clipping off the end of the extended wire. Normally you need less heat for small connectors, so the heat loss in the wire wrap is not an issue. Cliff Buttschardt K7RR

What type of tuner are you interested in building? There are many different circuits available depending upon your needs. Do you intend to use open wire feedline, coax, or just a random length of wire? If you want to be able to switch between different types of feedline, then the switching circuitry will probably become the most complicated part of the desing. I suggest checking out any edition of the ARRL Handbook or Antenna Book for options.

I agree with your comment on common mode currents. Also, with your
comment about the directional coupler. What it really amounts to is
that if the coupler has poor directivity (equivalent to not being
balanced for the impedance of the cable being used), some of the
forward wave is coupled into the reflected port. The resultant
apparent reflected signal depends on the relative phases of the
forward and reflected power and thus on the position of the coupler in
the standing wave. This phenomenon can also make the VSWR look better
than it really is if the two waves tend to cancel.

This discussion is a good example of the Internet at work. It's nice
to see that the ham radio newsgroup generally seems to be populated by
considerate people and not the nutcakes that wase bandwidth on a
couple of other newsgroups I follow.

>impedances at different points aliong the coax and you will get a
>different SWR with a 50 ohm source, depending on where you feed the
>coax. So your friend is correct if the load is not m,atched
>accurately.

No, the SWR is constant, and is a function of the mismatch at the load end only. That constant SWR is what causes the presented impedance variation along the line (due to transmission line transformer action). If you insert the SWR meter anywhere along the line, it will read the same SWR (discounting line loss). A SWR meter reads SWR, not impedance.

Internally, a SWR meter is a 50 ohm line section, so it merely acts as a short extension to the cable being measured. (If you try to measure 75 ohm line with a 50 ohm SWR meter, however, you'll be in for some surprises.)

Conversely, if you have an operating impedance bridge, you can measure the impedance at any point along the line, and given that, the cable length from the load to that point, and a Smith Chart, you can determine the SWR on the line (discounting line loss).

Now if the line has loss, and all real lines do, then you have to add a fourth variable, and the system becomes more complex. Instead of a constant SWR circle on the Smith Chart, now you have to follow a SWR spiral which approaches 1:1 as cable length tends toward infinity. The approach is asymptotic, and if cable loss is high, will quickly approach 1:1, but never quite reaches 1:1. If loss is low, the approach will be very gradual, and for moderate line lengths can be assumed to be a constant SWR circle.

(Incidently, this is a convienent way to measure line loss, just place a short or open at the load end of the cable and read the SWR at the source end, the closer to 1:1 it is, the higher the cable loss. There's a formula in the Handbook which will give you the exact loss in db for a given SWR and line length.)

For moderate lengths of good cable at HF (good cable, not RG-58), cable loss can be discounted and the SWR circle can be assumed nearly constant. At VHF+ however, even with good cables loss may become significant when the length exceeds several wavelengths and must be considered when analyzing line behavior.

This means that a low SWR is not necessarily a good thing. It can indicate a lossy system rather than indicating a good match. One way to differentiate is to look at the SWR curve over a band of frequencies. If it is broad and flat, the cable is probably lossy (or you have a dummy load for a termination). Real antennas are typically only close to design impedance over a narrow frequency range (typically less than 5% around the design frequency), so the SWR curve should quickly rise as it moves away from the center frequency of that range. Anyone who says he has a broad flat SWR is probably really telling you he has a pretty good dummy load for an antenna system.

(Note there are exceptions, antennas such as discones and log periodics present a near constant impedance over a large frequency excursion. But in general a low antenna system Q is indicative of low efficiency and high loss, IE the behavior of a dummy load.)

> I heard for a 5/8 you need to have a top hat, is this true? Also any
> info on whether this 5/8 is a good antenna comparing it to the quarter waveN3XZX Chris

altavoz: No hat required for 5/8 w. A 5/8w is much better for vert'
omni directional than 1/4w . Same coil for 1/4w but tapped a little
different . Radials must be 180 degrees, straight down, with
"wiskers" (going down 1/4w from feed point, some 1/4w radials at
45 degree angle...they form a cone).
A hat on 5/8 w will effect the pattern , try it.
For more gain, put a hairpin (<1/4w shorted stub) on top of 5/8 then
another 5/8w vert on top of that . Or the whole ant' a 5/4w and a
colinear stub pointing down (open end down , at the 5/8 w point)
Coax up thru "tube" Radial system.

>
> In this case, the length of the cable is critical
> to a given frequency.
>
> Steve KT4FY

altavoz: No, a 50 ohm ant' feeding a 75ohm coax will
cause a SWR into coax and towards the radio and an exact
length of coax will not reduce the SWR except as
attenuation factor over that length.

Well guys, I have to jump in here with my limited knowledge and 2 cents worth. It seems like the beam power pentodes were good up to a pretty high frequency and you would be better off with a large octal just because of plate power dissipation. Sure you could use a 12AT7 dual triode, but why, the little ones have the frequency response but no plate power. I think in general the idea is that the more grids you have the higher the frequency response. Triodes are usually low frequency with only one grid, Heptodes(?) with 2 grids a little more, and Pentodes are the king with 3 grids, 1 for control, 1 for electron bounce suppression, and 1 for capacitance neutralization.

I don't have my tube manuals handy or I could look this up. If you want I can at a later date look up what would be a good all around tube. I have RCA manuals from 1956, 1965, and 1976 (mostly those stupid compactrons), and an old Sylvania book about 1965.

Let me know if I can help.

==========
SSR (Solid State Relay). They are available in various ratings -
inside the little brick is a light-activated electronic switch, and a
solid-state light source (a LED). You supply activating current (a few
mils at, typically, 3 to 30 volts DC, and this switches "on" the SSR.
You can get them in AC and DC models, with really usable current
ratings. I see them at hamfests often.

I have applied a few, and they are easily activated by TTL levels. I
use some that are rated at 30 Amps 240VAC.

AFAIK, all the Radio Shack microphones have the FET built-in. That's
because the impedance of the electret mic itself is several hundreds of
megohms and can't drive a signal any distance because of the capacitance.
So the amplifier has to be very close to or inside the mic element.

altavoz: You dont need to cut in 1/2 wave multiples
since it wont change the SWR except thru a very small
increase due to decreasing attenuation over length.
H.F. has very low attenuation on RG8

Hi Bob, The Swan manuals reside here in Oceanside -- former home of
Swan.

Its too long to copy so if you will -- go to my home page listed below
and click on "HAM RADIO MFGRS AND SALES" scroll down to Swan -- there is
info on manuals and repair. I have no peculinary interest in these -- so
this is FYI only.

I have a Swan 350 -- great ole rigs.

Good Luck

Digi-Key carries the Panasonic line of microphone modules. They are smaller than Radio Shack mics, but must do not have leads. Doesn't sound like a challenge until you see how small they are, and this old man is getting blind anyway!

I've used them and they work great.

That's Digi-Key http://www.digikey.com

Look at the DigiKey catalog. They sell microphone capsuels for 70 cents to $2.00
depending on the frequency response needed etc. The mikes are made by Panasonic.
I noticed that DigiKey has a web site: http://www.digikey.com

have fun

Well, the Panasonic electret capsules are available through Digi-Key.
They started making their "flat" capsule about 12 years
ago. The original capsule has been discontinued and two
other models have taken its place. Most of the other common
capsules in the market don't have near the flatness in response.
I saw this when I saw the Digi-Key catlog and prompted me to
use and write up some applications which appeared in Speaker
Builder magazine around 1985. Alot of the larger less
accurate capsules have peaking around 6-7 Khz. Digi-Key
shows a simple circuit in their catalog. I don't know if
Panasonic offers any better data sheets or applications.
The use of the capsule will determine much of its performance
value. There is also another fellow who made up a version
called the Mighty Mike. That article and kit was in Speaker
Builder magazine and a kit available through the Old Colony
outlet. I don't know if there is an equivalent capsule
manufacturer. Most of the better ones achieve better S/N
ratio but are made by microphone companies. There is a fellow
on alt.sci.physics.acoustics, Johanson, who is
in the microphone business. Perhaps you could try that
group also.

> Hello, thanks to read my. I'm HB9ICC in Geneva.
>
> I'm looking for a program to calculate a parabola antenna.

The parabola program part is easy. What isn't obvious is that if you use simple analytical calculus, you can rotate the axis of the parabola from the usual plot, make the origin of the graph at 0,0 for the center of the paraabola and x,0 for the edge of the dish...you will find that for F/D ratios used in ham antennas, you can plot the whole thing on standard 8 1/2 inch width paper. No more laying the thing out by hand.

I wrote this up for the Central States VHF Society some 10 years ago. The whole program was about 10 lines of some version of Forth but I haven't got a clue where it's filed away. The math is not hard.

It is a simple and interesting exercise. Hope this helps.

I've had a couple of requests for examples directly addressing the length
of coax question:

At 28 MHz an antenna with an impedance of 70R +4J fed with 11.597 feet of
RG213(1/2 wave length at 28 MHz) has an impedance at the input of 69.28R
+3.76J. Virtually identical to the load, but even a halfwave of cable
does have some transforming characteristics due to it's loses. TLA
computes the SWR at load as 1.41/1 and at the input as 1.40/1.

The same antenna fed with 5.798 feet of RG213 (1/4 wave length at 28MHz)
has an impedance at the load of 35.77R -2.35J. An obvious transformation
of the impedance, however, the SWR is still 1.41/1.

If you feed the antenna with 1/2 wave of PERFECT COAX,(NO LOSSES) TLA
computes the impedance at input as 70.02R + 3.79J (The difference between

this and 70R and 4J can be attributed to rounding.)

Regards, Merv

Re your need for a switch to operate in a highly magnetnetic environment: have you considered pneumatic operation? There are switches available that can be operated by changes in pressure. Some of them are used for detecting water in the bilges of boats, and for actuation of bilge pumps.
Can you remotely activate the swtch by mechanical means? If so, you could use a mercury switch, which is basically two contacts inside a sealed tube which contains mercury. You rotate the tube to make or break the circuit.

> does make a difference.

altavoz: I get 271 "1/4 wavelengths" and that makes it an ODD multiple
of 1/4w and therefore it will radiate cause the open end of the coax
will see a short on the outside end of the coax at the radio end.
.66 VF RG58 , assuming a high SWR at load and 1:1 at radio.

> 2. 100ft of RG-58 on 28MHz with an SWR of 20:1 and *no feedline radiation*
> does make a difference.

altavoz: The diff we're talking of is trimming the line and in your
case trimming the line will increase the RF (feedline radiation)
on the outside of the coax By pulling down the Z seen on the outside
by the antenna . Trimming 1/4w will peak the FEEDLINE RADIATION.

A co. called Knowles makes quite good quality electret mic inserts. They
don't seem to have application notes, but they do have proper spec.
sheets. I don't have their details handy, unfortunately.

> folklore.
>
Has Tom actually read the book he recommends? Is this another case of do
as I say, not do as I do? ..... *Care and Feeding of Power Grid Tubes*
does Not discuss designing parasitic-oscillation suppressor devices.

When I was talking to an Eimac engineer in February, 1986, about
suppressing unwanted oscillations, he said that even though they (Eimac)
discovered that the reason for gold-sputtering damage in 8877s was an
oscillation condition, there were no Eimac Engineering Bulletins on the
subject. He said that the job of designing devices to suppress such
oscillations was the responsibility of amplifier engineers, not electron
tube engineers . He said: "that's your job".

.....so I got out my dipmeter and started investigating. Two years and
many experiments later, I wrote an article for QST, which was published in
October, 1988. A followup article was published in the September and
October, 1990 QST.

Are lower Q VHF suppressors needed? Take a look at:
http://www.vcnet.com/measures/bandswitch%2C%20parasitic-arced
After receiving a new bandswitch and lower Q parasitic suppressors, this
(3) 8874 ETO amplifier was successfully returned to service.

Another photo of a parasitic-arced bandswitch can be seen on page 33 of
"Parasitics Revisited" in the October 1990 issue of QST. The bandswitch
was removed from a TL-922A. After this article was published, Tom
telephoned me at the suggestion of QST's Paul Pagel. Tom said that such
bandswitch arcing could be caused by "cheap coax".

>of my hair and run out of connectors..

You don't say how small these connectors are, Thomas. For pins on 100 mil centers, I like to use a Weller soldering station with a 50 mil chisel tip. This transfers heat well while being small enough not to cause solder bridge problems. Weller also has tips with a long fine conical point that you can use for even smaller spacings, but that doesn't transfer heat efficiently. If the pins are sized for wires no larger than #30, then the fine conical tip will do, but for larger pins the heatsinking will be such that the smaller tip actually encourages solder bridging.

You need enough heat transfer to get a good rapid bond. This is critical. Make sure the tip you choose offers good contact and good thermal transfer. Of course keep it clean and well tinned too. A temperature controlled soldering station with short thermal lag is almost mandatory to get good results. The old Weller WTCPN is adequate, but Metcal and others make suitable units too. I stick with Weller because they are widely available and have a huge assortment of tips available for various size work. Most any industrial electronics supplier will stock Weller equipment. (And I notice that HRO just starting stocking Weller soldering stations and the Pyropen SMD rework hot air sources.)

Of course you should be using a suitable gauge of eutectic solder, err on the side of finer rather than larger, and I'd suggest some extra rosin flux. Joints have to be clean to give a quick secure bond. Don't be afraid to use a bit of extra flux to achieve that.

If you are working at a smaller spacing than 100 mils, I recomend you look at other options. If the pins are cup style, you might try tinning the pins and wires then sweating them together with a static hot air source. If the pin carrier is a thermoplastic, you might want to look at IDC technique instead of soldering. (Dip headers can be a particular bitch. Always install them in

a socket before attempting to solder or the pins will wander
in the softened plastic.)

Here's a tip which will prevent solder bridges and yield a neater
connection too if the pin spacing is no closer than 100 mils. Use
individual short pieces of heatshrink tubing on each lead. Once
you've soldered on the wire, slip the tubing down over the pin
and shrink it. Then go to the next wire. The heatshrink will
prevent a solder bridge, or a mechanical short, from occurring
to the pins you've already completed. (If you're using a static
hot air source, the heatshrink will also protect adjacent pins
from being desoldered while you're soldering the next one in line.)

If you're mass terminating a cable with a connector, make a fixture
to hold the work. This will make things lots easier. I often make
expedient fixtures out of wood. Take a piece of board and attach
a couple of scraps to it loosely with wood screws, spaced so that
they'll hold the connector and cable in the proper relationship.

Slip the connector under one of the scraps and tighten down the
wood screws (if the connector is round, drill and split the scrap
first so it will be a good fit). Now slip the cable under the other
scrap and tighten that down. Make sure you've stripped back enough
of the jacket to give you wire ends long enough to easily work with,
and start soldering.

Think about the order in which you're going to solder the pins so
that you'll still have good access to the last ones (you may want
to plan on rotating and reclamping the work halfway through). If
you're going to use heatshrink, be sure to slip that in place first,
of course. For the neatest work, I use short individual pieces of
shrink on each wire, and a larger piece on the complete cable.

Make sure you have a strong light illuminating the work so you
can see what you're doing, and use a magnifier or a jeweler's loupe
too if your eyes are somewhat old and tired like mine. I keep a 12 V
boxer fan on the bench to act as a fume extractor to keep fumes out
of my eyes (locate it to *suck* from the work rather than blow across
it, otherwise it may chill the work and make soldering harder). Arrange
your workspace so that you can rest your forearms on the bench, or on
a couple of sandbags on the bench. This will make you remarkably steadier,
and much less fatiqued. Take your time, this isn't a race. If you start
to get frustrated, back off, take a breather and then come back to the
work. You can do remarkably fine work if you'll just be patient and think
the project through first.

Gary

>wire of small diameter around your existing iron. The last turn is
>extended forward far enough to solder but not block your view. A chisel
>tip can be formed by simply your cutters and clipping off the end
>of the extended wire. Normally you need less heat for small connectors,
>so the heat loss in the wire wrap is not an issue. Cliff Buttschardt K7RR

That's a crude field expedient technique at best. The heat loss is a problem because the expedient tip has low thermal mass, and cools quickly when brought in contact with the work. If you can't quickly supply enough heat to make up that loss, you'll have trouble getting a good joint. If you just try to brute force it by wrapping it on a high wattage iron, the expedient tip will oxidize so quickly before being brought to the work that good heat transfer won't occur. If you must use copper as an expedient tip, keep it well fluxed and tinned at all times, and keep the thermal path as short as possible.

Here's an expedient tip that'll work better. Take a piece of 1 inch diameter CRS and chuck it in the lathe. Turn the end down to 50 mils for as short a distance as possible while still letting you approach the work. Radius back the shoulder for extra clearance. Part off at about a two inch length, center drill and tap the other end to fit on a 250 mil shaft threaded 1/4-20. Use a long 1/4-20 bolt for the shaft, and fit a wooden handle. File a chisel point on the 50 mil end.

Now you can heat the iron over a gas stove and use it to solder your connections. Return it to the stove between joints and keep it well tinned. The thermal mass of the large section coupled with the short thermal path to the tip will allow you to do good work. (BTW, that's why they're called soldering *irons*, you may need to keep several in the fire at the same time if you're doing production work, but be wary of having too many irons in the fire at once, you won't be able to tend to all of them properly.)

>altavoz: No, a 50 ohm ant' feeding a 75ohm coax will
>cause a SWR into coax and towards the radio and an exact
>length of coax will not reduce the SWR except as
>attenuation factor over that length.

You two are talking about different things. Sure, the SWR on
the cable will not be unity, but if you cut the cable to an
electrical halfwave (or multiple), you *don't care* because
the impedance seen by the source is a repetition of the
impedance presented by the load. The source doesn't care
about SWR on the cable, it only cares that it sees the
correct impedance presented to it.

In the case of a 100 ohm load and a 50 ohm source, an electrical
1/4-wave of 75 ohm cable will transform the load impedance to
50 ohms at the source end of the cable. The source will be happy,
the load will be happy, and we'll be real happy there is SWR on
the cable, because it is this SWR which makes the transformation
happen. A "high" SWR isn't always bad, in fact it can be downright
useful at times.

Capsule microphones? Do you mean Electret microphones? If so,
Digikey carries them by Panasonic. You can get spec sheets from
Digi-Key also for $1.00. Don't know if it will have apps notes in it
though.

A really crude but often effective estimate of a bipolar transistor's voltage gain is simply 38 times the voltage across the collector resistor. The beta of the transistor mainly affects the input impedance and, consequently, the power gain (assuming that the designer has eliminated the various negative feedback paths). I tried a 2N4401 with about 35 volts across the collector resistor and got a gain near 1000 which is a bit shy of 1330 but pretty impressive anyway! I could use higher current to swamp the collector shunt losses but then the input impedance would become hopelessly low. I wonder how well my small-signal 300 volt transistors would do!

2323. CASH FOR RADIO SUPPLIES

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-28 00:00:00 UTC
From: "Conrad R. Dery, Jr." <conradjr@bright.net>

Take a few minutes and read this. It could change your life!!!!

This is your chance to earn BIG BUCKS

This is for real....no gimmicks!!!

I read this article from a news group telling me I could make $50,000.00 in
as little as a month from an investment of only $5.
It sounds like a scam but it is legitimate. If you doubt it check out
Title 18 section 1302 of the U.S. Postal service and regulations.
It is --NOT--ILLEGAL--IT IS NOT A --CHAIN LETTER--IT IS TOTALLY
LEGITIMATE!!!!!!!!!
I decided that an investment of only $5.00, 5 envelopes and 5 first class
stamps was not going to break me even if I didn't receive any money back.
I can't guarantee that you will make money, who can, but the chances that
you won't are extremely small.

So here it is.....The procedure is simple

First.

Write your name and address on five separate sheets of paper.
Next write "Please add me to your mailing list" on each piece of paper.
Fold a ONE DOLLAR BILL in each piece of paper and mail one to each of the 5
following addresses:

---

1. ERIC FINCH, P.O. BOX 245 LUFKIN, TX 75901

2. KIP GRIFFIN, 349 W. WEBSTER, MUSKEGON, MI 49440

3. PETER SIMMONS, 668 CLAY #118, SAN FRANCISCO, CA 94111

4. JOE D'BELLA, 4611 TWISTED OAKS DRIVE #1916, RALEIGH, NC 27612

5. CONRAD DERY, 817 N. WASHINGTON ST., VAN WERT, OH 45891

Second

Remove the first name on the list and move the other four people up. For
example (5 becomes 4, 4 becomes 3,) etc....
Put your name and address as number 5
You can do this by re-typing this article or edit it and re-post it.

Third

Post your amended article to at least 200 news groups. This may seem like
a lot but it is easy to post to more than one at a time and there are over
17,000 different news groups so there is no shortage of space to post. The
more news groups the better your chances of being seen.

CONGRATULATIONS!!!!!!!!!!

You are now in the mail order investment business.
You will start to see results within 7 to 14 days
Remember, the more news groups you post to, the bigger your return will be.
You may want to get a post office box to handle all of your mail.
If you wish to remain anonymous you can use a pseudonym such as "The
Manager" or "The Investor", but be sure your address is correct!!!

How and Why the system works.

Out of every 200 postings you make you receive an average of 5 replies,
each with a dollar bill enclosed. Yes only 5, as an average.
It looks small at first but when you analyze it you see the beauty of your
investment.
With 200 postings you make $5.00 with your name at number 5
Each person who sent you $1.00 now makes at least 200 postings with your
name at number 4.
You have made $50.00
Your 50 new agents make 200 postings each with your name at number 3.
Now there have been a total of 10,000 postings. The average return is 500
at $1.00 each is $500.00
They make 200 postings each with your name at number 2.
Now there are 100,000 postings with your name on them.
Now expect 5,000 returns at $1.00 each...WOW $5,000.00
Finally 5,000 people make 200 postings with your name at number 1
You get a --$50,000-- return before your name drops off the list.
AND THATS IF EVERYONE ON THE LIST MAKES ONLY 200 POSTINGS!!!
Total possible income in one cycle = $55,555.00

From time to time, when your name drops off the list, you take the latest
posting that appears in a newsgroup and simply add your name and another $5
and your back in.

Remember 200 postings is only a guideline
The more you post, the more you receive

REVIEW

The cost to you--$5.00 + 5 stamps + 5 envelopes

There are millions of internet users and hundreds of thousands of new
customers every month which gives you millions of prospective agents.

17,000 + newsgroups to post your article to.

Read the instructions carefully and act fairly
That is the only way the system will work properly
Keep a list of everyone that sends you money and monitor the newsgroups to make sure everyone is being fair
Print this out and refer back to it in the future.

Get ready to make the easiest money you have ever earned!!!!

Good for Charles. After watching the off-base answers on this thread for a while, I wondered if anybody was going to come up with the straight-forward answer!

In fact it's not crude at all, and is theoretically exactly 39.5 V at "standard" room temp (20C, 68F) and 39.2 at the temperature I like, (22C, 72F).

The gain of a single stage is g_m * R, where R is the load. We know one of the most predictable things about a transistor is its transconductance, which can be derived from the physics of the transistor with the Ebers-Moll equation (see AoE pg 80 - take the derivative). The transconductance is dependent upon the collector current and is g_m = 1/r_e = I / V_T where V_T is kT/q = 25.3mV at room temp (20 deg C). Since k, T and q are all physical quantities having nothing at all to do with the transistor's design and construction, this is a very dependable parameter.

As Charles said, the voltage drop across the collector resistor is the key. This is because of ohms law, I = V / R so that g_m = I / V_T = V / (R * V_T) and the gain G = R * g_m = R * V / (R * V_T) and R cancels out leaving G = V / V_T. Neat huh!

So if Charles takes a 300V supply and biases his 300V transistor at 10V, so there's 290V across the load resistor, he'll get a small signal gain of over 11,000. !! Of course, this ignores the Early effect (pg 75), which does depend upon device design and will reduces this number.

In any amplifier it's always nice to have a low-impedance output, as can be had with a transistor emitter follower. Even tho a follower stage has a gain of only 1, there's a simple trick which allows very high gain for the two-transistor pair, without using HV transistors or 300V supplies. I leave this as an exercise for the reader!

Bill,

Compactrons CAN be very useful: they are fairly cheap, are the final stage in the development of vacuum tubes,
and can do a LOT in one envelope. Sockets are available from AES and other places.

Try em, you'll like em.

And whatever you do: Keep em glowing!

2331. DSSB from QRP Notebook

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-28 00:00:00 UTC
From: mlc@izzy.net
Message-ID: <552gs7$8il@izzy4.izzy.net>
Source record: 101315

I built the DSSB generator from the QRP Notebook, works great but I can't seem to null the carrier at all. For testing purposes I tapped off the oscilator in my newly finished DC reciever and used that as the LO to feed the DSSB circuit I took the output of the DSSC and fed it directly to the input of an old DX-150 reciever tuned to the correct freq.

While tuning the oscilator of the DC Reciever I could hear it in the DX-150 very strong of course. I turned up the mic gain in the DSSB circuit and voila Im making double sideband, I tuned the balance pot back and fourth but the carrier didn't change one iota. The diodes in the balanced modulator were measured for the same resistance but even if they were off I would think the 250 ohm trimmer would make SOME difference.

Any thoughts?

Has anyone else built this circuit and put it on the air?

Regards and thanks,

Tim, ka8ddz

The clock positions are dependant on how you locate the knob.
As the variable cap is turned through 360 degrees, it will vary from
a minimum C value, to a max C 180 degrees later, back to a min. You
get two peaks because you pass through the same capacitance twice.
If you had only one peak, with the cap plates fully meshed or completly
open, it would mean you were not reaching resonance, and needed either
more or less inductance in the paralleled coil.

: Since the author called out to use a smaller trimmer (50 pf) and a fixed
: value across the coil I assume he was trying to make the tuning easier by

: this? Does it matter as long as the trimmer peaks at two points.

Correct. Doesn't matter except with the cap passing through resonance
faster, harder to get the exact peak, and you might loose just a touch
of performance.

Wrong O buddy boy.

An electrical 1/2 of coax is a tried and true method of mesuring
the SWR at the antenna feed point remotely for exactly that reason.
Its totally invisible to the remote test gear. If you doubt it try it!

Now that I've got a couple DC recievers under my belt. I'd like to know:

How can I improve the sensitivity of one built for 80m? Does putting a pre-amp in front get you anything on the lower bands?

The tuned circuit I have for the front end calls for a cap across the coil with a trimmer to bring it in. I found that using a 100pf trimmer brings it into tune at both 10 o'clock and 2 o'clock. I assume then that it is within the correct range.

Since the author called out to use a smaller trimmer (50 pf) and a fixed value across the coil I assume he was trying to make the tuning easier by not having such sharp peaks with a higher value trimmer. Am I on track with this? Does it matter as long as the trimmer peaks at two points.

altavoz: You're assuming a choke . The thread makes more sense
if you dont assume a choke (i went all the way back to JOEL
GAMBLEs post)

I think he's saying a 440 signal into RG58 is a 1:1 NO MATTER
WHAT cause it's 100 feet long and that means it could be an
open circuit . I think he tried to get one past us by making
us assume that there was a termination .
Anyway the way to kill it is BALUN,steel wool, ferrite,
cut coax to a particular length (narrow BW), or offset feed
the antenna (bal ant has an unbal' point where you can hook
coax, and pattern does not suffer).
What i find amasing is so many novices worry about the
match , but not the radiation pattern . You can match
anything, even a 1/2w by stretching it a little to bring
down the R and that 2nd lobe is too small to hurt .
Radiation pattern on a J pole is bad but has a nice
stub to match it....so build a 5/8w using that stub to match
it. Problem is the standard way ("L")is just as simple.
Thanks for correcting my sloppy thinking, 73's

The maximum gain you can get depends on what circuit configurations you
allow. If you allow positive feedback, the answer is 'infinite'. Then again,
how many 'non-ideal' properties will you take into account? Finite output
resistance is easily allowed for, then comes internal c-b feedback
resistance, then capacitances. I think you need to define the problem more
closely in order to get useful responses.

>John <N3REY>
>Always QRP!

You didn't specify what you want, so I'll assume you mean a SSB radio
(as opposed to a-m or FM).

The PLL-synthesized SSB rigs made in the late 1970s and early 1980s are
going to be the easiest to convert... change one crystal and re-tune, and
you're on the air. I couldn't begin to name them all.

I've converted Cobra 148GTLs, Sears RoadTalker 40s, Penneys 6246s (I have
one of these right now), and many others.

Avoid the older 23-channel crystal-mixed rigs (too costly to convert).

I'm not familiar with any CBs that have scanning or memories (been out of
the CB market for about 20 years, since I became a ham).

Sure, you're still hearing the DC receiver's LO *directly*, so of
course you can't hear the carrier null of the DSB unit. Indicate
the null with an RF probe directly on the DSB unit output.

If you're using a proper low noise first stage in the audio circuit,
an RF preamp won't help sensitivity (though it can reduce backwave
from the receiver LO, and that may be worthwhile). Generally, the
problem at lower HF is not too little sensitivity, it is too much,
IE the receiver overloads from strong nearby signals, or even rectifies
them in the mixer (a problem with AM broadcast signals). A good preselector
filter in front of the receiver can help a lot. It *may* be worthwhile
to have a high intercept RF preamp in the middle of the preselector
to overcome insertion loss, and to suppress the LO backwave as mentioned
previously. I'd suggest a 3 section ganged preselector (top coupled)
with the preamp between sections 2 and 3, IE closer to the mixer than
the antenna. The preamp shouldn't have high gain, 6 to 12 db would be
about right, and should be biased for a high standing current to improve
its intercept. A CATV line amp transistor works well here.

>this? Does it matter as long as the trimmer peaks at two points.

You get two peaks because the capacitor is at partial mesh near both
ends of its range, and gives you the same capacitance value at each of
those points. Ideally, the capacitor will be at the correct value when
exactly half meshed, thus the two peaks would be exactly 180 degrees of
shaft rotation apart. You're getting resonance closer together than that,
which is telling you that resonance is occurring at greater, or lesser,
than half mesh, IE the capacitor is a bit too large or too small to give
you the greatest bandspread (depending on whether it resonates at lesser
than half mesh or greater than half mesh in the middle of the frequency
range you want to tune, look and see).

Depending on whether the capacitor is too small or too big, you can
parallel or series fixed capacitance with it to get it to resonate

at exactly half mesh in the center of your tuning range. Having it too small is best, and will give best bandspread and smoothest tuning provided you still have enough range to resonate at both ends of the desired tuning range (check that, you'd like the lowest end of the frequency range to occur at near full mesh of the capacitor, and the upper end of the range near the least mesh of the capacitor). It can require a bit of juggling to get it right. You can remove plates from a capacitor which is too big to get it in the right range, but it can be hard to put them back, so be careful to test as you go.

The *shape* of the capacitor plates can matter too. There are two styles available. One varies capacitance non-linearly with shaft rotation while the other varies capacitance linearly with shaft rotation. The former is preferred for broad tuning spans. The latter tends to bunch up the tuning near one end of the range if the tuning span is large. This is a nuisance when you want a linear tuning dial. Unfortunately, the latter style is the one more commonly encountered today in the smaller values. For narrow tuning ranges, the linear type is satisfactory. You can tell them apart by looking at the symmetry of the plate about the shaft. The linear type is symmetric, the "straigt line tuning" type is not. This is the same principle as linear and log taper (audio taper) pots.

I use the Avery brand laser transparencies. These are different
from the transparencies sold for copiers and seem to work better.
I'm told copiers are hotter, and require a different transparency
material. If you use copier transparencies in a laser printer,
you don't get as good a fusion of toner to the transparency.

I friend of mine just showed me a transparency he did on an Epson
Stylus inkjet printer. Looked really good. This may be a better
way to go. Note, inkjets need a special transparency material
or the ink will smear like crazy. The side the ink goes on has
a slightly rough feel.

I hope this doesn't need to be said, but of course you need to
print the transparency with a mirror image of the layout and
expose with the ink side toward the board. Otherwise you'll
get undercutting of the resist.

Hmmm. I have a MLA2500. It hasn't blown up yet, and the tubes still
seem to have plenty of life in them. With replacement tube prices
being what they are, I'd like to keep it that way. I'm open to
suggestions as to life extending improvements.

How about using ferrite beads over wires instead of resistors?
I've heard reports that they are almost purely resistive at VHF. Shouldn't
the HF bypass choke keep the beads out of saturation if the system is
properly designed?

Or, stepping a little further back, how about a distributed
design solution, perhaps with an integrated transmission line to reduce
the unwanted parasitic elements? After all, you do have to shield the
amplifier anyway--why not integrate the shielding with the circuitry,
instead of trying to make it invisible?

Greetings. "ha ha".. right. While that may be amusing to you, I am looking into getting a few CBs (portable jobs) for use during multi-car trips. This last trip was the end of my patience. It's either a CB in every car or I'm not going on another one of those.

You would, instead, suggest that everyone get a HAM license and a $400 transceiver... right? Dream on. The fact is that you use the right tool for the job. Most [snob] mechanics scoff at Chinese tools... and forget that I can weld those six $0.99 "vice-grips" into a custom tool that they can't even imagine.

[sigh]

WANTED:

Anyone want to unload some cheap hand-held CBs? I just need about 1 mile range... often less. 12V cord is a plus. Doesn't need 40 channels. Identical units a plus too. Budget, $35-45/unit. Any recommendations?

Take care.

This is NOT what Foote reported to me.
The unique thing about gold-sputtering is that the grid itself shows no
sign of heating. The only thing that displays any sign of high
temperature exposure is the gold plating on the grid. // Gold boils and
evaporates at over 2000 deg. F in a vacuum.

> >.....so I got out my dipmeter and started investigating.
snip...
>
> Why does a dip meter have to do with parasitics?

It is like a compass to a mariner--i.e., it points the way..

>Did you use the dip meter as a wave meter?

No. .... Every parasitic oscillation must be supported by a resonant
L/C circuit. A (lowly) dipmeter is ideal for helping to find the resonant
circuit that supports the parasitic.
If a dipmeter was placed near the anode-resonant circuit during an
intermittent vhf parasitc oscillation. it would undoubtedly be destroyed.
Thus, resonance tests are performed with the amplifier disconnected from
the electric-mains, with the dipmeter in osc. mode.
A (more elegant) full-power test for the frequency of parasitic

oscillation can be performed with a spectrum analyzer. Even when there is no parasitic oscillation taking place, with a pulsed drive signal applied, small damped-wave bursts of vhf energy can be seen on the analyzer at the transistion points when the drive signal is pulsed on and off. .(note: the spectrum analyzer is coupled to the anode-resonant circuit with a small wire probe, placed several inches away from the anode(s). The spectrum analyzer will sustain damage if it is connected directly to the anode circuit.)

Sounds to me like a Klystron. Foote worked in the Power Grid Division.
Klystrons are not power grid tubes, Tom. // You speak as though you
heard the conversation between yours truly and W. Foote. Are you psychic?

Mr. Foote said that during the testing phase of the development of the
8877, sudden failure took place. High leakage was observed in tubes that
were known to have had good vacuums shortly before testing began. He said
that when kaput 8877s were dissected, it was found that the high leakage
was due to condensed particles of gold that had evaporated from the grid.
When seen under a 50x microscope, these particles appear to be perfect
spheres. Foote said that the 8877 engineers determined that the
phenomenon was caused by an oscillation, most likely in the UHF range.

No, gold flaking or sputtering is a common (so far as problems go)
problem. It is a difficult metallurgy process, and many things can go
wrong.

The high power tube (that Foote misled you about) fell victim to heating
because of multiple causes. The tube was very large allowing it to support
an extremely high frequency internal oscillation. The grid was not part of
oscillators current path, and the anode and cathode current was so high
the oscillation was never noticed on the meters. The grid would sit there
and cook in a small area (from RF heating) for days and days at high
temperatures, without any external indication of a problem, until the gold
boiled off and ruined the tube.

That was the danger of that particular esoteric failure, the oscillation
was confined to the INSIDE of the tube.

A small tube will not support that mode of oscillation, plus the currents
are generally low enough that the user would see some indication of
failure. The tank circuits and tubes would never support the cavity mode
oscillations that damaged the tube Foote was thinking of.

By and large, the largest source of failures in tubes similar to the 8877
and 8875 are excessive drive or grid current or simple tube manufacturing

problems. Like any temperature related failure, grid damage relates to the amount of overdissipation and the duration of the overdissipation.

Early Dentrons had NO grid overload protection, as a matter of fact most had NO grid meter! They had high filament voltage, and poor cooling. They drove too easy, and had heater windings common to the high voltage transformer (making them prone to heater inrush damage). After seeing problems Heath had with an 8875-style (but conduction cooled) tube in the SB-230, it's a wonder any of these PA's survived amateur use. Not having a grid trip circuit or arc suppression in the anode was poor engineering.

As a matter of fact, adding a grid trip circuit and anode energy absorbing resistor to the SB-230 reduced tube failures almost 80 percent in field tests!

I see how you reached that conclusion, but I'd like to ask you to consider a few points.

The dip meter only tells you a system is resonant, what we really need to know is the impedance presented to the tube. For example, I have used resonant parasitic suppressors in applications where the operating frequency is very close to the self-neutralizing frequency of the tube. In that case a series resonant high Q L/C circuit (to ground through a damping resistor) or a damping resistor across a parallel L/C circuit will place the resistance effectively in circuit for the undesired frequency, while divorcing it from the circuit at other frequencies.

Placing the dip meter near the tank may tell us something is resonant, but it tells us nothing about the loss or impedance of the anode to chassis path. The correct device is a network analyzer, a grid dip meter is a little too crude.

In any event, resonance in the anode does not guarantee oscillation. The grid must also be resonant at or near the same frequency, and the feedback path loss must be less than the overall gain of the system at the frequency of oscillation.

> A (more elegant) full-power test for the frequency of parasitic

>wire probe, placed several inches away from the anode(s). The spectrum
>analyzer will sustain damage if it is connected directly to the anode
>circuit.)

I've looked at PA's in a similar way, and never seen a oscillation that starts and stops with drive. Of course I'm not saying it can't happen, only that I've never seen it while looking at literally hundreds of different PA's over the last twenty years or more. Part of normal FCC type acceptance is testing PA's for spurious emissions, and good design dictates testing for spurious case radiation of VHF or UHF energy. I would be suprised if such oscillations (if even remotely common) never showed up in tests looking at signals radiated from the PA enclosure.

I'd like to make one important point, a wire probe creates a VERY non-linear frequency vs amplitude response in the analyzer. The correct probe is a capacitive divider with the low Z analyzer swamped out by a large capacitance at the bottom, and a small C coupled directly to the tank. This "evens up" the frequency response.

If the 50 ohm analyzer input is left as the dominating impedance of the capacitive divider's bottom leg, and a long wire probe is used, the response can be highly peaked at higher frequencies. The slope of the frequency response can be much larger than expected from a simple C/R voltage divider. You very well might have seen the sudden waveform change overloading the input amplifier of the analyzer, or some other momentary anomaly over-exaggerated by a non-linear probe response.

But even if that wasn't the case, when the gain of an oscillator exceeds the feedback loss (including less than perfect phase) it oscillates, when gain is less than feedback loss, it stops oscillating. Since the gain of a tube decreases as anode or grid current is increased, the natural effect is the oscillator finds a point of equilibrium where output stabilizes. If a class AB tube oscillates at full drive, it will continue to oscillate when drive is removed. As a matter of fact, it would be difficult to intentionally design a system that work in the opposite manner!

Every VFO works this way, often using the "natural" level limiting that occurs in an oscillator. The oscillation is not absent, only to suddenly ring up to a large uncontrolled value causing something to explode. Oscillators don't work that way.

73, Tom

Hello all,

Awhile back, I posted the following for a friend, at the time he sold all the radios he was willing to give up. Now he wants to sell the rest, AND has DROPPED the price $150!!

A friend of mine has a "bunch" of Yaesu Dual Band Radios which he would like to sell at a great price. He purchased them for the emergency response group which he is envolved in and has decided to sell them and get radios which do not have as many functions and features. His policy appears to be "the simpler the better" for emergencies.

Yaesu FT-530 Dual Band HT
Yaseu Standard 2 Watt Battery
Yaesu Hi-Power 5 Watt Battery
Yaesu Rapid Charger (for both of the above batteries)
Yaesu Standard Battery Charger
Yaesu External Speaker/Mic
Yaesu Standard "Rubber Duck" Antenna
Antenna Specialist's Dual Band "Rubber Duck" Antenna

Each of them have had the out-of-band modification done by a local Southern California Dealer at time of purchase. They will be sold on a first come first serve basis.

He is asking $320.00 for each radio. They may be placed on a credit card for no additional fee, and there is a $5 shipping charge to anywhere in the US via UPS insured ground.

If you are interested, please call Steve at 818-502-0000.

(I am posting this for a friend who does not have access to the newsgroups, please do not write me back.)

Hi Zak,

Parasitics occur for various reasons in various circuits, it is pretty difficult to speak of solutions in Carte Blanche terms.

In article <32760A8D.3AF4@arrl.org>, Zack Lau <zlau@arrl.org> writes:

> How about using ferrite beads over wires instead of resistors?
>I've heard reports that they are almost purely resistive at VHF.
Shouldn't
>the HF bypass choke keep the beads out of saturation if the system is
>properly designed?

First we have to understand why the oscillation occurs. In typical HF (and lower) circuits using small power grid tubes (below 50 kW) , the problem centers around the grid connections. At some frequency, the grid is no longer a good shield. The grid, even though grounded, "looks like" it floats for RF. Like any resonant circuit, the impedance generally peaks at one frequency.

If the anode circuit happens to be resonant at the same frequency, the tube can oscillate. The usual effect is much like a TPTG oscillator. The suppression must be in the primary VHF signal path through the plate tuning capaciator, not in series with the RF plate choke.

What we need to do is add some loading to one of the resonant circuits, so the loss exceeds the gain. Once that is done, the stage becomes stable.

Since this is almost always (with a proper layout) a single frequency area problem, we want to add as much damping as we can over the undesired frequency range.

The problem with ferrites is the transition from inductive to resistive behavior (loss of Q) is generally very slow as frequency is raised. What we want is an abrupt change, where loss is very low at desired operating frequencies (allowing good efficiency) and suddenly the loss is very high at the undesired frequency.

We also need a resistance in the suppressor that properly terminates the anode. The ideal resistance depends on the impedance of the anode to chassis path through the plate tuning capacitor. The higher the impedance of that path, the larger the loading resistance needs to be. The impedance transformation due to the anodes shunt capaciatnce and series inductance also affects the ideal value of this load resistance.

In general terms, we want the anode to chassis path to be as short as possible, since we want the lowest possible distributed resistance and

reactance at the operating freqiuency and above. This allows us to use a small resistance value in the suppressor.

In the ideal case we would have the most rapid "insertion" of damping resistance possible as frequency is increased, short wide grid leads and short wide anode connections. All resitance should be concentrated at one area so it can be adjusted to the correct value for maximum damping.

Different tubes tend to oscillate at different frequencies, tubes with long grid structures and long internal leads tend to oscillate at 100 MHz or lower, while other tubes like the 3CX1200Z7 and 8877 almost never oscillate because system gain falls off well before the self-neutralizing frequency is reached.

With a tube using long internal leads suppression is more difficult, since the tendency to oscillate is often close to the operating frequency. For example 572B's and 811A's try to oscillate below 50 MHz, often as low as 25 MHz in a poor layout. So if we wanted a stable amp we would have to use a very large reactance in the suppressor.

Ferrites might work if the tube self-neutralizing frequency is far above the operating frequency, but likely will not be the best choice in amateur HF applications using tubes with grid resonances in the low to mid- VHF range.

Always nice to hear from the master, however is this really the straight
forward answer we're looking for? A transformer can offer voltage "gain".
What separates an active device like a transistor from a passive device
like a transformer is the possibility of *power gain*. Given a power
gain, we can easily make practically any voltage we like with a step up
transformer in the drain circuit.

2368. CMOS Super Keyer technical info?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-29 00:00:00 UTC
From: Monty Wilson <nospam@see.signature.part>
Message-ID: <E023p7.I6r@twisto.eng.hou.compaq.com>
Source record: 101260

Hey gang I just looked through archive articles for some
information on the Super Keyer from Idiom Press. I found
lots of people who were pleased with the product in its
various forms, but not a word about modifying the keyer
for use with a grid-block transmitter, or for relay output
so it can be used for both grid-block and direct transmitters.

I got mine second-hand and it did not come with any technical
information at all; the tutorial and user manual are mostly
concerned with the command set, etc. For all
I know it can be configured at assembly time for either
keying method, but that information would only be covered in
the construction article which I don't have. In any event, I
would like to modify the keyer to give it a relay output so I
can switch easily from one rig to another without worrying
about whether it's grid-block or direct, the relay to be
powered from an external source so the battery does not run
down. For this I need to know the current handling ability
of the keyer's output transistor so I don't fry it.

Does anyone here have this information?

Please reply,

2369. Problems making PCBs

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-29 00:00:00 UTC
From: larsm@lin.foa.se
Message-ID: <32763f3c.31207011@news.lin.foa.se>
Source record: 101261

Hi
I am etching some PCB's with various results, and the major problem seems to be the plastic film that I use in my copier. To get the "least bad" result here is how I do it:

1 Print a papercopy on my laser
2 copy to plastic film on a copier, this tends to give better contrast rather than use the plastic film in the laser directly
3 Exspose a P20 PCB
4 Develope the P20
5 Etch

The problem seems to be in the plastic film that is not enough transparent, and the black areas not enough black giving poor contrast and the areas that I want to be removed often have some P20 left on the copper despite the time I try to develope the traces.

Have anyone found a transparent plastic sheet that can easily be obtanined and be used in either a laser printer and/or a copier to give fair results?

>oscillation condition, there were no Eimac Engineering Bulletins on the
>subject. He said that the job of designing devices to suppress such
>oscillations was the responsibility of amplifier engineers, not electron
>tube engineers . He said: "that's your job".

As I understand it, you were talking to Willis Foote. He was a
"specifications engineer" working in the customer return department, not a
design engineer.

If you call Eimac, you'll find gold sputting is a problem due to a variety
of causes, most of which are physical. The "parasitics thing" delt only
with heating in a very high power UHF TV transmitter tube, NOT the 8877.
That's why there was never a bulletin on the 8877 (or any other small
tube).

>.....so I got out my dipmeter and started investigating. Two years and

>was removed from a TL-922A. After this article was published, Tom
>telephoned me at the suggestion of QST's Paul Pagel. Tom said that such
>bandswitch arcing could be caused by "cheap coax".

The damaged switch could have been caused by a multitude of operating
problems, not just bad coax. Anything that unloads the tank circuit can
cause an arcing problem, as can selection of a component that simply is
inadequate for the job.

Voltage at the anode end of the tank can exceed the dc supply voltage by
many times if the tank becomes unloaded or improperly loaded. The ideal
condition for creating this effect is excessive loading capacitance and/or
a low Z termination of the tank output (with a pi-network).

This condition shortens the anode conduction angle to less than 180 degrees (if the original class is AB or lower angles) and allows the tank to store energy, ringing the vltage up much like in a switching regulator. Eventually, if equilbrium isn't acheived first in dissipative losses, something gives.

The SB-220, when improperly loaded, can produce over 4 kV peak on the input end of the tank. The tube peak anode voltage is over 7 kV. Until something "gives" or the energy falls back in equilbrium, the voltage builds. Unfortunately it is often the tuning capacitor or bandswitch that arcs.

This effect can be measured and documented, it is not a matter guessing the cause. The TL-922 is the same.

On the other hand, you would have everyone believe the VHF energy can build up to a very high voltage across the very low VHF impedance of the plate tuning capacitor, high enough to arc the switch over. The real effect of the capacitor and residual inductances is actually to step VHF voltages DOWN, not up. After all, that's why the tank adds VHF harmonic suppression.

Wouldn't a tank that fits your theories (allowing high VHF voltages, ie high VHF bypass impedances) have very little VHF harmonic suppression? And if so, how did it pass FCC tests with such marginal case shielding?

Yep I had this problem. I use acetate sheet that is opaque and diffuses the ultra violet light. I also experimented with lots of small off cuts of PCB until I found the correct time duration for the brand of PCB and brand of acetate sheet.

I actually print the PCB layout direct through my laser onto the actetate sheet with the laser printer toner control set to maximum. Even so large copper areas don't come out too well. Thin (25 thou) tracks do. The laser non-linearity is taken account of by an XY compensation in the CAD package.

> ka8ddz Rochester Hills, MI

Hi Tim OM,

A preamp will increase the sensitivity of the receiver. Normally,
the atmospheric noise is high enough on the lower bands like 80M so
that it easily overrides the internal noise in the receiver. A DC
receiver
with ring diode mixer front end will have a noise figure somewhere
in the 10-15 dB range. IF the band is unusually quiet, this receiver
internal noise can be heard, and under those conditions, a preamp
can be helpful. In other words, it does no good to amplify both
the signals and the atmospheric noise together; you just end up where
you started. BUT, if the receiver's internal noise is dominant, then
adding additional gain in the front end with a low-noise preamp will
help the received sig/noise ratio, by reducing the receiver's noise
figure. The price paid for increased sensitivity is reduced dynamic
range, making the receiver somewhat more susceptible to overload by
strong local signals.

Hope this helps; all this is in various ARRL and other books on
receiver design and construction.

>circuit (not grounded grid) .
>73, Jesse, W6KKT

Jesse, I used 4-1000's years ago, and did IMD tests on them.

They were cleaner in cathode driven AB1 than in conventional grid driven AB1, but not "state of the art" in either configuration. I measured IMD suppression of less than -30 dB 3rd order for a conventional IMD test (below a single tone) at 1000 watts PEP input.

It varied a bit with the particular tube tested. I take it your figures are for IMD against PEP (a non-standard method)? If so, you might come close to -36 if the cathode is driven or a unbypassed resistor is included in the cathode to add negative RF feedback. Without proper RF feedback you likely would not get that figure.

Be sure to properly select the grid resistance to keep the exciter operating at optimum output power, and regulate the voltages good.

What circuit are you talking about? Is it the Phasing SSB rig on page
164, or something else in the book?

The problem that you might be having is that your test setup is unable
to notice the null. A sensitive receiver near the actual transmitter
might be picking up the carrier oscillator directly, so no matter how
much you try to null the carrier, it sounds like nothing is happening.

I recall this happening to me years and years ago. I used a similar
setup, and nulling the carrier was a problem.

Try using an rf voltmeter of some kind (a scope, a real RF voltmeter,
a VOM with a diode detector, or even a sensitive panel meter
fed from a diode detector), on the output of the balanced modulator.
I think this will show a null.

If it doesn't, then you have to go back and look at what might
be imbalanced in the balanced modulator. Such as the coil winding,
components feeding the circuit, etc. The carrier balance control(s)
are there to overcome slight imbalance in these things, but if for
some reason something else is grossly incorrect, then it may not
have enough range to overcome the imbalance.

Also, layout can affect balance. It shouldn't make the difference
between no balance and some balance, but once you get some balance,it
will effect the extent of the null that you can get.

That's what has always puzzled me - why do these "parasitic
oscillations" happen so intermittently?

When the amplifier goes bang after sitting quietly under essentially the
same operating conditions for several hours, the real question is: why
didn't it happen hours ago? Are the conditions for oscillation soooo
very special?

I've been reading Mr. Measures' articles for years (along with the responses from some of the ARRL people and the manufacturing engineers).

After careful study, I've developed a profound respect for Mr. Measures' technical knowledge and his objectivity in reasoning. While some of his "critics" are knowledgeable in certain areas, they usually get off-track, get lost in their own arguments, or end up throwing smoke. Some of their responses have been so obviously biased or technically inept, they must surely be embarassed when they see their comments in print.

One example of "smoke" was the safety issue. One of Mr. Measures' suggestions for keying an amplfier would have resulted in 110 volts on the "keying" line to the amplifier (a circuit that I use, by the way). Anyone who can't handle the safety issues involved in a low-current 120 volt line shouldn't be fooling with linear amplifiers. The gist of Mr. Measures' article that contained the keying suggestion was a simple, cheap way to achieve QSK. Lacking a better idea (they had idea's, but not simple or cheap or better), they felt compelled to "take a shot" with this lame safety argument.

If my ARRL membership depended on the "cheap shot response" that appeared as a result of his (Mr. Measures') provacative article in QST, I would no longer be an ARRL member.

Nobody seems to want to answer the poor guy's question.

For current gain, many transistors have gains of 100-200 and I've seen some up to around 400 or so. I'm sure some specially-made units can be had with even higher gains. There are Darlington-type units with much higher current gains, but they are really two (or more) transistors in a single package, so they don't really qualify as "a" transistor.

For voltage gain, the answer depends more on the load in the collector circuit than the transistor, assuming you're using a common emitter amplifier. With a very high load impedance, gains of tens of thousands are possible, although designing a usable circuit with that much gain can be tricky, to say the least.

For power gain, the results depend more on the rest of the circuit than on the transistor, but gains of 15-20 db are not unreasonable and a clever designer can no doubt squeeze out more than that. Again, this is not an area where you want to push the limits because single-stage, high-gain amplifiers are naturally unstable and will try to oscillate (this is where the cleverness comes in).

Hope this helps.

Well, remember that these things are built to price, and a pretty
low price at that. The filters usually aren't very good, and of
course they're channelized. The ones made in the last several years
are hard to move off the CB channels, which may not matter if you're
using it with a homebrew transverter, but they're also generally
hard to modify to slide *between* channels. Older units could
usually be modified easily so that the clarifier moved transmit
as well as receive. HyGain and Cobra both made units that were
easy to convert. I'd be checking garage sales for older SSB
units by either company.

There's usually a little bitty ad in QST for a book on 11m->10m
conversions. Getting a copy of that might be worth your while.
It should point you toward radios that are easy to modify.

>
>

I tried 'em all.

Here is how I do it.

Layout the PCBoard with Harvard Graphics 3.
Using an HP DeskJet 500C print the layout on a transparency.
AN HP550C is better because it prints true black.
Only HP sheets work for me. The Premium kind.
You now have a very fine detail negative or positive (I use negative).
The output menus in HG3 gives you many ways to print
once you get the hang of it.
Coat (I laminate) the board with the resist.
Shoot the PCBoard thru the negative for 5 minutes with a PE-2 bulb at 12 inches..
Use the proper type (POS - NEG) and develope the board
Etch as hot as you dare! And agitate.

Note: Laminating the resist to the PCBoard eliminates all that messy stuff.
You get perfect coating at 1.5 mil with the laminate process.

You don't need a $1000 laminater to do it either.
The Ibico units (at Office Depot) work great. (<$250.00)

I get my chemicals and laminate from Kepro. 1-800-325-3878

OK, Tom, a quick quiz. What is the inductance of the film resistors we use in our parasitic suppressor retrofit kits? BTW, Tom, you can not find out anything by cutting one of these resistors. Scraping the blue coating off is the technique that works.

Straight one-inch copper tubing has more inductance than most hams realize. It takes surprizing little of it to make 100nH.

Carborundum "non-inductive" resistors are no less inductive than a piece of copper tubing of the same length and diameter. The typical "non-inductive" Carborundum resistor has approximately the same inductance that is required for the suppressor inductor. Thus, if you put such a resistor in parallel with a typical 70nH suppressor inductor, you loose the essential stagger-tuning effect that lowers the Q of the parasitic suppressor. .

Please do not disregard situations where the line can be used for
matching. Take a quad loop, with 100 Ohms input impedance.
A quaterwave of 75 Ohms line, with a few coiled turns for a balun
will save you an antenna tuner. And there a other situations
where matching is simplified (less losses) when using a defined
length of line for tranformation.

Ceramic panel mount variable capacitors, 4-17pF, Nickle plated brass
These make great variable caps for VFO's. They are single bearing but beat
the aluminum palte variables for stability. Surplus Sales of Nebraska had
these in their catalog for $20 each!

$4.50 each or 10 for $35

I also have some 2 1/2 " vernier dials marked 0-100. They are available at
$6
each and quantity is limited.

Excellent example here. I fed a triband quad with this method for several years. It was the only way I could get a GEM Quad to play with a single 50 ohm coax to three tuned 75 ohm quarter wave stubs.

>
> Any thoughts?

Don't know how sensitive the DX150 receiver is or what the output level
is
from the DSB module, but don't you think plugging the exciter directly
into the receiver input might just overload it a tad?? Assuming a
conservative -10dBm from the exciter, even if you achieve an unrealistic
40dB carrier suppression from the exciter, the receiver will still be
getting
S9+ on the suppressed carrier!

How about sheilding the exciter and adding some extra 30dB or so
attenuation
between the exciter and receiver. (free space works well)

Charles Wenzel, <wenzel@wenzel.com> said...
>
> A really crude but often effective estimate of a bipolar transistor's voltage
> gain is simply 38 times the voltage across the collector resistor.

Actually it ranges from 1 to 100+ and depends more on the emitter resistor ratio to the collector resistor. Power transistors can have a Beta or current gain of only 10, where most generic 2N3904 NPN types will run about 100, some special types go up to 200 or so, and Darlingtons can go up to about 10,000, but don't count on frequency response. Assuming the current gain is enough the voltage gain is going to be the ratio between the emitter resistor and the collector resistor, unless you have bypassed the emitter resistor for High frequency gain. The math is easy until you start trying trick configurations.

> The beta of the transistor mainly affects the input impedance ....

Actually, you can get a gain of 100,000, not that it will be good for much. No emitter resistor and a 1 meg collector resistor. As soon as you pass the Base-Emitter thresh hold the 1 meg will saturate. Useless, but a demonstration.

You guys have been reading too much, or not enough. the bandwidth is very much tied to the gain and current passed through the transistor and 100uA to 5mA is what most want unless you only want audio. If you try the 0 ohm emitter resistor and the 1 meg collector what you will have is a very nice switch, but not an amplifier. All of the manufacturers do something a little different with their transistors, to change the gain, bandwidth, current, power, etc., which all affects the capacitance and response. I suggest you get a modern reference from someone who is still making them (not ECG, or SK replacements) and look at the variety that can be had. Motorola is big on R.F. power transistors and still makes a line of small signal. Siliconix, (now Temic, Eoropean) makes F.E.T.s of all kinds.

If you want a front end R.F. amplifier, try this. Get a junction FET, N, depletion mode and put a 150 ohm to ground on the source side. Bypass this with a .01uf and 10 ohm to ground. Feed the gate with the top output of a tuned circuit tank with variable cap, (whatever band you want). Wind your outside antenna with about one turn around the tuned tank circuit with the end grounded. This will give good coupling into the tuned circuit without affecting its' Q. Take the Drain lead and tie it to a 2N3904 or whatever H.F. NPN you have. Take the base of the NPN and tie it to +5 volts, bypassed by a .01uf or smaller. Take the collector of the NPN and tie it through a 1K (experiment for your design) and take the collector output to a cap (D.C. isolation) to the input to to your receiver. You will find that the Q factor is so high that it will pull most receivers plus and minus 10 or 20 KhZ before they figure out what is going on. I used a 10" diameter loop for the tuned circuit and picked up a lot of

stations without any outside connection. The outside antenna was just icing on the cake.

Try it, have fun. I'm an E.E. so I have the data books on most REAL 2N type transistors if you need them.

E.C.G. and S.K. I gave up on a LONG time ago, ditto Rat-Shack, since all they have is repackaged T.I. types, which I suspect failed a test or 2 and where sent to the R.S. (good enough for them bin). Tandy is based in Texas, so is (obviously, Texas Instruments).

If my spelling is off tonight, well hell, I can't type that good after 2 beers.

Bill Baka

Hoping I could help without muddying the waters.

2398. Hallicrafter Transmitter Manual

Where did you get those 3000 volt transistors? If the circuit is biased to get 5 volts across the 1 meg. the gain will be near 200. And the circuit IS useful for driving a crystal earphone from a crystal radio source. The gain really doesn't go up with the collector resistance as you suggest.

<<clip>>

>I suggest you get a modern reference...

When Dr Hill publishes his next book, I will.

<<clip>>
> Hoping I could help without muddying the waters.

Many may be wondering why I referred to my estimate of a common-emitter's gain as "crude" when Dr. Hill suggests that it is pretty accurate. Well, here are my top ten reasons:

10) Hoping for the Bill Gates "Analog Isn't as Good as Digital" award.
9) Qualifier required by legal staff.
8) "Re: What is a capacitor?"
7) Bad habit of using solder for jumper wires.
6) Here in Texas, "crude" is good.
5) Third copy of "Art of Electronics" stolen from library - had to wing it.
4) Still confused by that Kelvin - Centigrade thing.
3) Suspicious of devices with no screen grids.
2) Spock-like brain works to six digits.
And the #1 reason:
1) Only on week 'till election - don't want to blow it now!

I mounted a 2 meter ant. to my window on a van and I would like to move it. The problem is that it is stuck to the window with the adhesive that came on it. The antenna was made by Radio Shack and the guys there don't have a clue if it can be removed without damaging the antenna. Anybody got any ideas? Thanks.

There's an important issue that has not been mentioned.
If your SWR is 1:1, coax length is unimportant.
If it's not, then the impedance looking into the coax is a function
of the length. Draw a (constant SWR) circle on a Smith Chart. As you
change length,

you move around that circle. As long as your transmiter can match any impedance on the circle, you're OK. With a high SWR or with a modern no-tune rig, you might find that the rig behaves significantly differently depending on the coax length. SWR doesn't change, but the matching network required to drive the coax sure does.

Having said that, I suggest you put your effort into making the antenna 1:1 rather than messing with the coax length.

Doug,
I couldn't locate anything to help in my data books (only a few new enough to cover low dropout regs). Best I could do was a 0.6 volt drop regulator chip from TI. It would, however, only supply 750 ma. I got around a similar problem (ATV Tx =flaky when batt low) by building an step-up switcher - down regulated. It is set to supply 13 volts reg while the input can be from about 10 to 18 volts. ...73, Woody

2405. switching power supply mod

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-10-30 00:00:00 UTC
From: God@Provide.Net
Message-ID: <55724i$6tb@news.provide.net>
Source record: 101275

I have an old switching power supply from a large computer.
It says 5 volts at 50 amps. I was wondering if I could modify it so
that it would deliver say 12 volts at 20 or so amps.
What do ya think about this:

1. change the output filter caps to 16vdc

2. tear apart the trans and rewrap the secondary with smaller
guage and proper turns ratio for higher E and lesser I.

3. change resister divider network that feeds the sampler/error amp

Will it work? Will I have saturation problems?

Any advice would be appreciated.

Thanks, Brett

Of course, Bill, emitter degeneration, or any other type of feedback will reduce voltage gain. However, since here we're discussing "what is the maximum (voltage) gain that you can get..." it's clear that introducing gain-reducing components or techniques will simply muddy the waters.

> Power transistors can have a Beta or current gain of only 10, where most
> generic 2N3904 NPN types will run about 100, some special types ...

It cannot be stated often enough that in a properly-designed common-emitter amplifier stage, the current gain of the transistor should not be a factor in determining voltage gain.

> Darlingtons can go up to about 10,000, but don't count on frequency response.

This is totally misleading and simply incorrect. The proper use of a darlington transistor circuit does not reduce frequency response, but often enhances it.

> ... Actually, you can get a gain of 100,000, not that it will be good for
> much. No emitter resistor and a 1 meg collector resistor. As soon as you
> pass the Base-Emitter thresh hold the 1 meg will saturate. Useless, but a
> demonstration.

Now you've really got me going! Bill I think these generalizations are not useful and inaccurate. First, without an emitter resistor, the quick formula for low-frequency voltage gain of an unloaded common-emitter stage, adjusted for a given load resistor voltage V, is just G = V * kT/q and as this formula shows, the actual value of the load resistor has nothing to do with the gain.

Let's make some amplifiers with different collector load resistors. We'll assume a +9V supply and bias the transistor collector at +4V, by means not covered here. Emitter to ground. We'll assume 5pF of collector capacitance, and a low-Z driving source.

collector collector frequency theoretical
resistor current response voltage gain comments

--------- --------- -------- ---------- -----------
10k 500uA 3.2MHz 200 AM-band radio stations
100k 50uA 320kHz 200
1Mohm 5uA 32kHz 200 9V battery lasts a long time
10M 0.5uA 3.2kHz 200
22M 0.11uA 1.5kHz 200 light-powered circuits
100M 50nA 320Hz 200 "good for a demonstration"

Note that the voltage gain doesn't change. Also note the perfectly acceptable 32kHz bandwidth with a 1M-ohm collector resistor. Are the low-current versions useless except for a demonstration? Of course not. Many real-world applications get along well with sub-kHz signals and are forced to work with very low supply currents. I won't even start the long list.

Now Bill, wrt "Actually, you can get a gain of 100,000 ..." I should point out that a more complete formula for CE stage gain is G = g_m * (R_L || r_o) where r_o results from the output conductance of the transistor due to the Early effect. The actual fact is that the Early effect may well prevent a gain of 25,000 let alone 100,000 in a single-transistor CE amplifier. {This is not to say a higher single-stage gain cannot be obtained when more than one transistor can be used.]

If this thread had serious attendance by semiconductor device engineers (which I am not) we'd see that "Early voltage" would be at the heart of the discussion. Early voltage, VA, or VAF, is very important to the bipolar transistor designer, right along with f_T, beta and base resistance. See for example, http://fnctsrv0.chips.ibm.com/products/ams/tech/Tquickref.html

The beta-VA product is an industry figure-of-merit parameter, often reported by industry gurus like Frank Goodenough. It's a critical issue for example in designing high-performance current sources. E.g. see http://www.ee.washington.edu/conselec/W94/aleph/aleph498.htm

In conclusion, Bill, I'd like to say that we could all use a little more reading!

Keep the faith.

Easiest way use a heat gun like those you use for shrink tubing. Don't get it too hot about 120 F is enough for most glues. Remove the excess glue by scraping with a stainless steel single edge razor blade. Stainless blades won't scratch the glass, it has to do with the way stainless micro machines.

Gary asked about the MLA. One reason I suspect you've had such good life is you know how to operate the amplifier, many or most Hams do not.

If you recall that the root of our disagreement about the tetrode articles. My position was tetrode PA's were not as forgiving in the hands of the general population. With focused beam cathode triodes, they have some tetrode-like charicteristics. One is that a very slight amount of mis-tuning or excessive drive will cause grid current to skyrocket. While grid current changes slowly with load adjustment in tubes like the 3-500Z, it varies rapidly in the 8873-8875 series. Not only is the potential for excessive grid current by mis-tuning increased, but the grid is many times smaller in mass. It takes less time to heat the grid (low thermal inertia), and it has less area to dissipate unwanted heat. It is also closer to the hot cathode.

If any amplifier needed grid dissipation protection, it was the MLA. Yet some MLA's had no grid meter at all, let alone an overload circuit. To give you an idea how quickly a tube like that can be ruined, I wasted a 3CX800 in abouta matter of seconds when I was prototyping a 3CX800 PA. I hadn't installed the grid trip circuit yet, and was doing some tank changes. After three or four SHORT hits with a 100-150 mA of grid current, the tubes were history. When I cut one open, the gold was boiled off the grid.

Not having electronic grid protection is a mistake. A fuse is not fast or reliable enough to control dissipation (you can find data on failure times with various overloads in a Buss catalog).

Other than that, and Dentrons failure to include a surge limiting resistance in the anode lead (it should be a 25 ohm or larger energy absorbing type of resistor with a high voltage breakdown), Dentron amps shared a few other common flaws:

1.) Voltage at the heater pins were often excessive (and don't run it too low or you'll strip the cathode)

2.) The bleeders were carbon resistors, they age down in value unevenly, and eventually cause the electrolytics to fail. Bleeders should be metal film or wire wound, with a value of bleeder current normally (since they equalize the caps) 10 to 20 times greater than the expected leakage current in the caps. (The formula actually must include the safe voltage delta allowed across the caps and the leakage current delta expected, it's ohms law...I'm sure you can figure out the method since the goal is to never have the voltage rating of any cap exceeded due to leakage resistance tolerances)

3.) Cooling was marginal in most PA's

4.) They used 300-400 volt resistors across the HV diodes

5.) Tank Q was goofy on some bands (that really only hurts efficiency a tiny bit)

6.) Input circuits were lacking, or located too far from the tubes, or had the wrong values for a proper match

It wouldn't be a bad idea to measure the filament inrush on a triggered scope, since the filament is run off a very large transformer. Heater/filament damage is accumulated thermal damage, so failure depends on the number of times you cycle the filaments off and on as well as the amount of overload. Just to be safe, you might check it. Two times operating value for inrush virtually elimates any chance inrush life shortening, although if the filament isn't cycled off an on a lot more can be tolerated.

The easy way to measure this is clip the isolated scope probe across a small area of filament wiring on one side of the filament and click the amp on from a cold start several times (I use a triac that triggers at zero voltage, because that allows the filament to "feel" the impact of the entire full first cycle, and gurantees maximum inrush) watching the voltage drop (it represents current).

Almost any amplifier with a separate transformer is OK for inrush with no other protection as long as the transformer is marginal for the filament current rating.

You could try VERY CAREFULLY using a hot air gun to heat up the window around where the antenna is mounted and see if that softens the adhesive. Be VERY uniform with the heating so as to not crack the window.

Alternatively, perhaps you can find a solvent that attacks the adhesive used, and keep applying it while slowly making repeated passes at the edge with a single edged razor blade.

Otherwise, live with it attached or destroy it to remove.

Hi Zak,

In article <32776DBF.4618@arrl.org>, Zack Lau <zlau@arrl.org> writes:

>Being a "single frequency area problem", what do you think about using
>inductive resistors in a clever design?

That's allready being done, in the AL1200 and some commercial applications. Because the 3CX1200A7 is so difficult to stabilize, a small series silver mica is used to tune a inductive resistor to resonance at the parasitic frequency.

The circuit looks basically like this:

```
L
anode -----((((((------------------------][-----plate tune cap
^ ^
^ --][--WW--^
C R
```

L is a small inductance in series with the anode to tank path, C is the cap that resonates the resistor path, and R is an INDUCTIVE metal film resistor.

If you model this or do it long hand you'll see the current will shift very rapidly into the resistor when L in combination with C approaches parallel resonance, and R's inductance in combination with C approaches series resonance.

This gives excellent suppression with minimum dissipation on the operating frequency. (Patent was applied for, I need to check to see if it was ever granted yet)

>While not everyone has
>a network analyer for alignment, why not use an antenna analyzer
>as an inexpensive adjustment guide?

The MFJ analyzer works well for some applications like this because it covers the normal range HF tubes oscillate at, 20-150 MHz. The anode impedance, when the suppression circuit is properly designed, is even within the useful impedance range of the device. It would be a long post to tell someone how to use it in multiple applications, however.

BTW, ferrite beads would not need to be in the dc anode current path. Saturation Rick L. brought up would still be a concern, especially on ten meters where the output capacitance of the tube is the primary source of tank input capacitance. The fact the anode capaciatnce is part of the tank places ANY component or wiring between the tube and the tank in the path

of high circulating currents at the operating frequency. Any additional loss at the operating frequency de-Q's the tank and reduces harmonic suppression, and the high VAR currents tend to cause stress on the components. I sure would stick anything dissipative at the operating frequency (including a ferrite bead) in that path, except as a last resort.

Great thinking and suggestions from you Zak and Rick L !!

RE: Shielding:
Spurious radiation is not the problem. The most common type of vhf oscillation in HF amps. is not continuous, Zack. It is intermittent because there is virtually no resistive load--i.e., something has got to give, and often does. Here's why: With virtually no load, the vhf energy runs amok in the front end of the HF tank circuit, typiclly resulting in arcing at the tune capacitor, and/or the 10m and 15m contacts on the bandswitch. If they exist, as is the case in the 922, include the tune capacitor-fixed padder contacts for 80m and 160m. Since the amount of vhf energy probably exceeds 1kw in large amplifiers, destruction can result. For a picture of the nauseating details see *QST*, Sept. 1990, page 33. Another example can be seen in Figure 12 at http://www.vcnet.com/measures

The voltages that can result from an intermittent vhf oscillation are impressive. For instance the TL-922 uses a tuning capacitor that tests out at well over 5000vdc. The max. RF peak voltage across this capacitor is normally around 2700v with the electric-mains supplying 240v to the 922. Other manufacturers of similar amplifiers typically use a tune capacitor with only 60% of the air gap in the 922's tune capacitor, so the safety factor is awesome. However, when the 922 oscillates at 140 MHz,

the tune cap. can arc. If you are lucky enough to see this happen, the arc is purple---a strong indicator that vhf voltage is present.

W1AW had a TL-922 that arced it's tuning capacitor so much that some of the plates melted. The tuning capacitor was replaced. Parasitic Suppressor Retrofit Kit s/n 293 (5/23/89) was reportedly installed. No complants yet. Any comments would be appreciated, Tom.

Good question, Gary.

Obviously, electrocution of owner, caused by owner forgetting to unplug the amp.,prior to owner putting hands therein, could be classified as a danger---but so could using a curling iron in a bathtub.

Accusations without a foundation are spurious emissions, Tom. I would like to hear the details about ruining $500 tubes, and details about equipment damage.

I have seen ferrite vhf attenuator beads purportedly used as vhf parasitic oscillation suppressors in HF amplifiers However, as Rick says, they are easily saturated by dc current. Another problem is that they have a well deserved reputation for being non-linear devices. Verily. I inadvertently generated TVI at 555MHz, a.k.a. Ch. 28, from my 7MHz signal. This was the result of a saturating ferrite core. When I looked at the transmitted 7MHz waveform with an oscilloscope, it was abundantly obvious that the waveform was Not a sinewave.

Hello! I've got some awesome news that I think you need to take two minutes to read if you have ever thought "How could I make some serious cash in a hurry???" , or been in serious debt, ready to do almost anything to get the money needed to pay off those bill collectors. So grab a snack, a warm cup of coffee, or a glass of your favorite beverage, get comfortable and listen to this interesting, exciting find!

Let me start by saying that I FINALLY FOUND IT! That's right!. I found it! And I HATE GET RICH QUICK SCHEMES!! I hate those schemes like multi-level marketing, mail-order schemes, envelope stuffing scams, 900 number scams... the list goes on forever. I have tried every darn get rich quick scheme out there over the past 12 years. I somehow got on mailing lists for people looking to make money (more like: 'desperate stupid people who will
try anything for money!'). Well, when I was a teenager, these claims to 'get me rich quick' sounded irresistible! I would shell out $14.95 here, $29.95 there, $24.95 here, and another $49.95 there. I had maxed out my new CircuitCity Card AND my Visa...I was desperate for money!! So, I gave them all a chance but failed at every one of them! Maybe they worked for some people, but not for me. Eventually, I just tossed that JUNK MAIL in the trash when I got the mail. I recognized it right
away. I can smell a money scam from a mile away these days...or so i thought. I believed I could sniff out a scam easily. WAS I WRONG!!...I LOVE THE INTERNET!!!

I was scanning thru a NEWSGROUP and saw an article stating: 'GET CASH FAST'!! I thought..."Here on the Internet?? Well, I'll just have to see what schemes could possibly be on the internet." The article described a way to MAIL A ONE DOLLAR BILL TO ONLY FIVE PEOPLE AND MAKE $50,000 IN CASH IN 4 WEEKS! Well, the more I thought about it, the more I became very curious.
Why? Because of the way it worked AND BECAUSE IT WOULD ONLY COST ME FIVE DOLLARS (AND FIVE STAMPS), THAT'S ALL I EVER PAY....EVER!!

Ok, so the $50,000 in cash was maybe a tough amount to reach, but it was possible. I knew that I could at least get a return of $1,000 or so. So I did it!! As per the instructions in the article, I mailed out ('snail mail'for you e-mail fanatics) a single dollar bill to each of the five people on the list that

was contained in the article. I included a small note,
with the dollar, that stated "Please Add Me To Your List."
I then removed the first position name of the five names listed
and moved everyone up one position, and I put my name in position
five of the list. This is how the money starts rolling in!
I then took this revised article now with my name on the list and
REPOSTED IT ON AS MANY NEWSGROUPS AND LOCAL BULLETIN
BOARDMESSAGE AREAS THAT I KNEW. I then waited to watch the
money come in...prepared to maybe receive about $1000 to $1500
in cash or so....But what a welcome surprise when those envelopes
kept coming in!!! I knew what they were as soon as I saw the
return addresses from people all over the world--most from the
U.S., but some from Canada, even some from Australia! I tell
you, THAT WAS EXCITING!! So how much did I get in total return?
$1000? $5000? Not even!!! I received a total of $23,343!!!
I couldn't believe it!!

I now have a brand new black Acura Integra to speak for, due to
this!! Now after almost 8 months, I am ready to do it again!!!
Somaybe it was possible to get $50,000 in cash, I don't know,
but IT COMPLETELY DEPENDS ON YOU, THE INDIVIDUAL! You must
follow through and repost this article everywhere you can think
of!
The more postings you achieve will determine how much cash will
arrive in you rvery own mailbox!! It's just too easy to pass
up!!!

Let's review the reasons why you should do this: The only cost
factors are for the five stamps, 5 envelopes, and the 5 one
dollar
bills that you send out to the listed names by snail mail
(US Postal Service Mail). Then just simply repost the article
(WITH YOUR NAME ADDED) to all the newsgroups and local BBS's you
can.
Then sit back, and enjoy walking (you can run if you like! :o)
down your driveway to your mailbox and scoop up your rewards!!
We all have five dollars to put into such an easy effortless
investment with SPECTACULAR REALISTIC RETURNS OF $15,000 to
$25,000
in about 3-5weeks! So HOLD OFF ON THOSE LOTTERY NUMBERS FOR
TODAY,
EAT AT HOME TONIGHT INSTEAD OF TAKEOUT FROM McDONALDS AND INVEST
FIVE
DOLLARS IN THIS AMAZING MONEY MAKING SYSTEM NOW!!! YOU CAN'T
LOSE!!

So how do you do it exactly, you ask? I have carefully provided
the most detailed, yet straightforward instructions on how to
easily
get this underway and get your cash on its way. SO, ARE YOU READY
TO

MAKE SOME CASH!!!?? HERE WE GO!!!*** THE LIST OF NAMES IS AT THE
END
OF THIS ARTICLE. ***OK, Read this carefully. Get a printout of
this
information, if you like, so you can easily refer to it as often
as
needed.

INSTRUCTIONS:

1. Take a sheet of paper and write on it the following: "Please add my
name
to your list". This creates a service out of this money making system
and
thus making it completely legal. You are not just randomly sending a
dollar
to someone, you are paying one dollar for a legitimate service. Make
sure
you include your name and address. I assure you that, again, this is
completely legal! For a neat little twist, also write what slot their
name was in: "You werein slot 3", Just to add a little fun! This is all
about having fun and making money at the same time!

2. Now fold this sheet of paper around a dollar bill ,(no checks or
money
orders), and put them into an envelope and send it on its way to the five
people listed. The folding of the paper around the bill will insure its
arrival to its recipient. THIS STEP IS IMPORTANT!!

3. Now listen carefully, here's where you get YOUR MONEY COMING TO YOUR
MAILBOX. Look at the list of five people; remove the firs tname from
position one and move everyone on the list up slot one on the list.
Position 2 name will now move to the position 1 slot, position 3 will now
become position 2, 4 will be be 3, 5 wil be 4. Now put your name,
address,
zipcode AND COUNTRY in position 5, the bottom position on the list.

4. Now upload this updated file to as many newsgroups and local bulletin
boards' message areas & file section as possible. Give a catchy
description
of the file so it gets noticed!! Such as: "NEED FAST CASH?, HERE IT
IS!,"
or "NEED CASH TO PAY OFF YOUR DEBTS??," etc. And the more uploads, the
more money you will make, and of course, the more money the others on the
list will make too. LET'S ALL TAKE CARE OF EACH OTHER BY BEING HONEST
AND
BY PUTTING FORTH 120 PERCENT INTO THIS PROFITABLE & AMAZING SYSTEM!!!
You'll reap the benefits, believe me!!! Set a goal for the number of
total
uploads you'll post, such as 15-20 postings or more! Always have a goal
in mind!!! If you can UUE encode the file when uploading, that will make
it easier for the people to receive it and have it downloaded to their

hard
drive. That way they get a copy of the article right on their computer
without hassles of viewing and then saving the article from the File
menu.
Don't alter the file type, leave it as an MS-DOS Text (***.txt) file.
The best test is to be able to view this file using Microsoft's Notepad
for
Windows 3.x or WordPad for Windows '95. If the margins look right without
making the screen slide left or right when at the ends of the sentences,
you're in business!

5. If you need help uploading, simply ask the sysop of the BBS, or"POST"
a message on a newsgroup asking how to post a file, tell them who your
Internet provider is and PEOPLE WILL ALWAYS BE GLAD TO HELP. I would try
to describe how to do it but there are simply too many internet software
packages with slightly different yet relatively simple ways to post or
upload a file. Just ask for help or look in the help section for
'posting'.
I do know that for GNN, you simply select 'POST' then enter a catchy
description under the subject box, choose 'ATTACH', selecting 'UUE' and
NOT 'TXT', then choose 'Browse' to go look for the file. Find your text
file CASH.TXT and click on it and choose 'OK'. Place a one line
statement
in the main body section of the message post screen. Something like
"Download this to read how to get cash arriving in your mailbox with no
paybacks!," or whatever. Just make sure it represents its true
feasibility,
NOT something like:" Get one million dollars flooding in your mailbox in
two days!" You'll never get ANY responses!

6. And this is the step I like. JUST SIT BACK AND ENJOY LIFE BECAUSE
CASH
IS ON THE WAY!! Expect to see a little money start to trickle in around 2
weeks, but AT ABOUT WEEKS 3 & 4, THE MONEY STORM WILL HIT YOUR MAILBOX!!
All you have to do is take it out of the mailbox and try not to scream
too
loud (outside anyway) when you realize YOU HIT THE BIG TIME AT LAST!!

7. So go PAY OFF YOUR BILLS AND DEBTS and then get that something
special
you always wanted or buy that special person in your life (or the one you
want in your life :)) a gift they'll never forget. ENJOY LIFE!

8. Now when you get low on this money supply, simply re-activate this
file again; Reposting it in the old places where you originally posted
and
possibly some new places you now know of. Don't ever lose this file,
always
keep a copy at your reach for when you ever need cash. THIS IS AN
INCREDIBLE TOOL THAT YOU CAN ALWAYS RE-USE TIME AND TIME AGAIN WHEN
CASH IS NEEDED!

9. (This comment added by Ron Markarian) Hell dude, this is great,
just send the money and wait like 1 week, then all of a sudden, BOOOOOOM!
Mail flood FULL of dollar bills. Hahahaha...its great

****** ******* ****** ********* ****** ******* ******* ***** *******

Hey Gary, give me a break! Remember, I only chimed in with the (gory) details after waiting a few days and seeing their absence. Didn't you think it useful? Anyway, with an attractive lob like that, who could resist a smash return?

Of course adding a transformer would change the whole story! Surely you can see most of us on the thread assumed voltage rather than power gain was the question (although no detail was stated), and that it was "transistor only." After all, as you said, with a transformer, you can get voltage gain, without any transistor at all! No load defined? Near infinite turns ratio - tuned? Consider the arguments and flames that would produce. So without detailed limits it becomes a senseless question.

> What separates an active device like a transistor from a passive device
> like a transformer is the possibility of *power gain*. Given a power
> gain, we can easily make practically any voltage we like with a step up
> transformer in the drain circuit.

Exactly, Gary. Isn't that a question without a real answer? Hey, create a new thread: "What's the maximum power gain from one transistor?" But, I'll probably stay out of that mudpit!

As for me, despite my well-known love of transformer design, somehow I can't appreciate your transformer form of the question. Instead, the idea of considering the capabilities of a few small inexpensive components (rules out a transformer)... now, that's more compelling.

In article <measures-ya023180003010961006480001@news.west.net>,
measures@mail.vcnet.com (R.L. Measures) writes:

>Accusations without a foundation are spurious emissions, Tom. I would
>like to hear the details about ruining $500 tubes, and details about
>equipment damage.

I can give a few specific examples, but I'm sure this would quickly turn from a technical discussion to personal "bashings". I would prefer to talk about the cause of problems, and the cures, rather that specific examples.

Since there are several suggestions that might cause damage or reduce reliability, and some are fairly involved they deserve to be discussed in isolated responses. Discussions are always clearer when they are point by point. Givin enough time, we'll get to the areas of concern. With that in mind:

In article <measures-3010961224430001@port20.vcnet.com>,
measures@mail.vcnet.com (R. L. Measures) writes:

>RE: Shielding:
> Spurious radiation is not the problem. The most common type of vhf
>oscillation in HF amps. is not continuous, Zack. It is intermittent
>because there is virtually no resistive load--i.e., something has got to
>give, and often does.

Oscillators do not work that way Rich. If the feedback loss (including less than ideal phase shift) is less than the overall gain, a system will oscillate. Let's look at a typical GG triode. The primary path for oscillation if via the anode to grid capacitance (remember anode to cathode feedback is degenerative. It reduces gain and helps stabilize the PA).

At some frequency above the typical operating frequency of the tube, the combination of shunt grid capacitance and series grid inductance forms a parallel tuned circuit. The inductance is made up of the grid, the grid leads, the socket, and the connection from the socket to chassis. Shorter and wider leads, along with a small grid, increases this frequency.

If the anode of the tube (inside the tube) has a high impedance at or near the same frequency as grid resonance, and if feedback capacitance is high enough, oscillation can occur.

We have to understand what sets the gain of this oscillator. It is the anode impedance, (as it appears inside the tube), and the grid impedance. When the tube is sitting at idle, drawing minimum anode current (but in conduction) the anode impedance is highest. The same is true for the grid.

The grid has an extremely high impedance when it isn't drawing current, limited only by stray losses. If the grid draws current, the grid impedance drops very rapidly. If anode current increases, anode impedance drops (less abruptly than the grid, because it is biuased into current at idle).

When these impedances drop, feedback is reduced. This is one reason why oscillators stabilize at one level.

So you see, it isn't that the stage just sits there waiting minutes, hours, days or years to suddenly oscillate when a big peak comes along, because that big peak actually reduces the gain!

You can see this effect easily by removing suppression and forcing the PA to oscillate. If a PA is brought just beyond the edge of stability, VHF oscillations will cease when drive is applied.

> Here's why: With virtually no load, the vhf energy
>runs amok in the front end of the HF tank circuit, typiclly resulting in
>arcing at the tune capacitor, and/or the 10m and 15m contacts on the
>bandswitch.

Let's think a little bit about this. The VHF impedance of the plate tuning cap is very low. It is on the other side of the series inductance of the anode to tank lead. In order to generate VHF voltages of thousands of volts, many amperes of VHF current would have to flow. I find it a far stretch to imagine that occuring to the extent 5 kilovolts of VHF energy appears acorss the low reactance of the tank capacitor, when you tell us it can't occur at HF where the series impedance is lower and the shunt impedance higher!

> If they exist, as is the case in the 922, include the tune
>capacitor-fixed padder contacts for 80m and 160m.

I find it even more difficult to believe the padding capacitors for 160 will arc from VHF signals. Tell me the value of those caps, and let's run some numbers to see how plausible that postulation really is.

>The voltages that can result from an intermittent vhf oscillation are

>the tune cap. can arc. If you are lucky enough to see this happen, the
>arc is purple---a strong indicator that vhf voltage is present.

An HF air gap arc is the same color as a VHF arc Rich. You might be confusing this with neon gas, it changes color with frequency being yellow or orange at low frequencies and purple at higher frequencies.

My Sony ICF-SW 7600 radio (Italian version) covers the following frequency range 150-285 KHz step 3 KHz, 531-1602 KHz step 9-10 KHz selectable, 3850-26100 KHz step 5 KHz, 88-108 MHz FM step 50 KHz.

The American version of the same radio covers the LF,MF and HF frequencies with the range 150-29995 KHz. I would liKE to obtain the same HF frequency range as that available on the American version but the frequencies 1602 - 3850 KHz and 26100 - 29995 KHz are not receivable on the Italian version!

The radio is controlled by CPU, it has a PLL utility, is equipped with a keyboard and can store 10 items in memory. The receiever is 48055 and 455 KHz double version and demodulates AM and SSB.

At power on the CPU checks the jumper configuration (LW, step 9-10 KHz in MW, SW, FM). Setting the LW jumper to OFF extends the frequency range from 285 to 531 KHz, while setting the FM jumper to OFF extends the FM range from 76 to 88 MHz step 100 KHz. Setting the SW jumper to ON or OFF has no effect, the frequency range remains 3850-26100 KHz in both cases.

* Does anybody have the ICF-SW 7600 schematics?

* Does anybody know how to extend the frequency range from 1602 to 3850 KHz and 26100 to 29995 KHz?

Please send your reply to my e-mail address, as detailed below.

Thanks.

Chalp Maurizio Olivetti (Italy)

I couldn't agree with Mr Hill more completely. I have been waiting for
someone to mention Va/Vt. I generally do not respond to questions of
this nature, but felt compelled upon reading Mr. Hills posting.

As a practical example consider the following which
will be somewhat specific to a typical Bipolar IC process,
but can be applied to transistors in general, BJT, MOS JFET.

Bias a Lateral PNP transistor with a vertical NPN current source. Let
the early voltage for the two devices be 20v and 200v respectively.
Assume the collectors are held at some voltage within their linear
range by a device with an infinite input resistance.
The voltage gain can be expressed as gm*R where gm = Ic/Vt,
and R is the resistance at the collector node. In the
case of assumed infinite load resistance, the resistance on
the node is the parallel combination of ro from the NPN
(output resistance of the current source) and the ro of the
PNP common emitter, (the output impedance of the gain device)
ro NPN = VaNPN/Ic and roPNP = VaPNP/Ic. Doing the math I conclude
that the total output resitance on the collector node is 18.18v/Ic. Now
multiply that by gm, Ic/vt and you get (18.18/Ic) *(Ic/vt) or 18.18/Vt,
about 700v/v (assume all numbers are valid at 25C). If
some cascoding or degeneration techniques were utilized to
increase the
output resistance of the current source, the total output
resistance would approach
20v/Ic, or simply VaPNP/Ic. This leads to the simple yet useful conclusion
that the maximum voltage gain from a single transistor stage will
not exceed Va/Vt. For the aforementioned devices that would imply
770 for the PNP and 7700 for the NPN. In practice achieving Va/2Vt is
more typical for an actively loaded, non cascoded common emitter
stage, as described above. Often times this is aggressive,
and loading must always be considered.

I'd guess anything goes, if it involves just simple R C and real (bipolar)
transistors. And, I'd imagine it rules out oscillators. Now, controlled
positive feedback: Hmmmm. Is there a one-transistor (no transformer) circuit
configuration for this?

The idea that the 3CX800A7 grid structure could be elevated to over 2000 degrees F by 150mA of grid current is not logical. 150mA times the voltage present is simply not going to make enough power to bring the grid up to gold-boiling temperature, .Tom. Did you ever wonder why the grid itself did not show indications of exposure to high temperature? The most likely answer is that the surface of the gold plating was heated and the underlying metal was not. This is what Eimac told me.

Have you ever heard of skin-effect? Do you realize how hot 2000 degrees is? At such temperatures, things don't just turn red, they glow bright yellow. Some ceramic glazes are fired at 2000 degrees. I once put some stainless steel wire through the peep hole in my ceramics kiln to see what would happen. It disintegrated.

Stephan's Law says the amount of energy required to increase the temperature of a radiating object is T^4. It might be fun to measure the mass of a 3CX800A7 grid, and calculate how much power would be needed to raise that mass to 2000 degrees.

I would like to work the microsats but do not wish to spend $2000 for
a FT-736.

So, I am looking for plans for a 2m xmitter and a 70cm rcvr pair that are
both microprocessor controlled (for auto dopler compensation) and capable of
9600bd FSK FM (mode JD). I don't care about front panel display or anything.
Kind of a 'microsat data brick'.

Anyone ever seen anything like that?

How about just a PLL controlled pair that I could add a BASIC Stamp
to for uP control.

Dave Covert, KB5GOG

Hi Rich,

It's fun to do lot's of things, but better to look at facts.

In article <measures-ya023180003110960335460001@news.west.net>,
measures@mail.vcnet.com (R.L. Measures) writes:

>The idea that the 3CX800A7 grid structure could be elevated to over 2000

>present is simply not going to make enough power to bring the grid up to
>gold-boiling temperature

The grid meter does read the true effective current, but the voltage is
not indictated except by direct measurement of the average cathode to
anode voltage over the portion of the cycle when the cathode is negative
compared to the grid.

In a grounded grid amplifier, with the anode mistuned, negative feedback
is removed and both the duty cycle of the grid and grid to cathode voltage
(and hence current) increases.

It's very easy to exceed the thermal limitations of the grid in the
3CX800, since the dissipation rating is only a few watts. If you like, we
can calculate the temperature rise of the grid and prove this, although
Eimac has already done this as part of the specs and gives it to us as
allowable grid dissipation.

At 150 mA of grid current in a typical HF PA, a single 3CX800 has a
measured grid dissipation of almost 20 watts. That's almost 5 times the
maximum rated dissipation of the grid.

I find it remarkable that you expect no damage from this severe an
overload, since even a rugged and thermally massive high temperature anode
located a large distance from the hot cathode wouldn't survive operation
at five times the rated dissipation for more than a few seconds (with an
internal anode tube) or minutes (with an external anode tube).

Heat caused by grid dissipation is concentrated in the very fine grid
mesh. This mesh has almost no thermal mass, it is designed to be as open
as possible so it doesn't block the cathode to anode path, except by it's
electric field.

Heat is only conducted from the grid via the path through that very low
mass mesh, or via radiation effects.

It's no surprise the plating disappears first, because normal
deterioration of materials, especially materials that are quickly heated,

occurs from the outer layers first.
Gold has a melting point of 1063 degrees C, and the base material used in the grid structure has a melting point between 2600 and 3400 degrees C (depending on the alloy).

I find it difficult to understand why you insist RF skin effect has something to do with the Gold deterioration, when the outside of the grid (where the Gold is) gets heated first, heated most, has by far the lowest melting and boiling point of any material used in the tube.

If that isn't enough, the underlying base material has lower thermal conductivity, reducing the thermal rise of the inner material. Since the Gold is directly heated, and thermal conductivity is lower in the underlying structure, the Gold quite obviously gets hotter and is damaged far faster than anything else for this reason alone.

I wonder how you justify your theory that only a UHF signal could damage the Gold, in light of well documented facts like melting points, thermal conductivity, and heat conduction?

It's only natural the grid is going to show Gold damage if overdriven from any cause.

Hi,

I wonder if anyone has (or knows where i can get hold of)
technical information for a Motorola MT700 FM handi.

I've got one of these units at present, it cost me a couple
of pounds at a local car boot sale, it seems to be working fine.
TX is 461.625 / RX is 456.125 with a 110.9Hz tone squelch unit.

I'm interested in converting it down onto my local 70cms repeater
freq. (433.325) and would be grateful if anyone can give me
some info.

Cheers,
Richard

I have a compactron in use right now in a transmitter! I'm using a 6T9 in a classic 80/40m circuit taken from the 1968 edition of ARRL's How To Be A Radio Amateur. I believe this circuit also appeared in the 1972 Handbook. It runs 4 Watts output on 80m and 40m CW, crystal controlled (of course!). This is the second variation of this circuit that I've built, and it works really well. The 6T9 is a triode/pentode pair in one envelope. I'm using the triode as the oscillator and the pentode as the PA. It's a two-stage transmitter, but with only one filament to feed, and only one tube socket to install and wire up. Give the Compactrons a try!

Tom: The term "capacitor-fixed" should have been "fixed-capacitor".
Sorry for the typo. It should have read:

>>With virtually no load, the vhf energy
>>runs amok in the front end of the HF tank circuit, typiclly resulting in
>>arcing at the tune capacitor, and/or the 10m and 15m contacts on the
>>bandswitch. If they exist, as is the case in the 922, include the tune
>>fixed-capacitor padder contacts for 80m and 160m.

Question: Am I talking about arcing the fixed-capacitors or arcing the
contacts?

You can buy a product called TEC-200 film from:

Meadowlake Corp.
P.O. Box 1555
Oneco, FL 34264

The stuff comes in 8.5 by 11 inch sheets. 5 sheets cost $4.95 plus $1.75 postage; 10 sheets for $6.95 plus $2.00 postage; 25 sheets for $16.00 plus $3.00 postage, etc. I just got some and have tried it once. It's not perfect, but is a lot less messy than ironing on from a paper copy and dissolving away the paper in Chlorox solution. With practice it might be possible to turn out some pretty nice PC boards.

does a superregenerative receiver count? I forget if it has a transformer
or not, but that is a circuit that doesn't oscillate without an input
signal,
yet provides tremendous output signal - to input signal ratio.

I have heard of people using Vellum (i.e. translucent drafting paper,
it feels kind of like a plastic).

I have also heard of/and tried using several transparencies one
of top of each other to get the necessary darkness.

One thing to remember is that just because you can see through the
transparency doesn't mean that the UV rays will pass through it very
well.

Also make sure that the toner side of the image is face down on the
resist.

You can also take your art work to a print shop and have them make
a line print (a high contrast black and white print). You might be
able to do this yourself by exposing your transparency onto ortholithic
film (Kodak makes this - available at a good Black and White
camera/print shop). Ortholithic film is a high contrast black and white
film - this may help compensate for the low contrast transparency.
You will need the special developer that goes with the film. The film
is easy to work with as it is safe to use under the standard
yellow/orange B&W safelight.

Am interested in homebrewing a 10 meter Linear Amplifier...

I have investigated converting a 'CB foot warmer' for 10 meters... but I do not care for the construction style nor the harmonics that these things create....

Does anyone have a GOOD schematic for a 10 meter linear amp in the 200-300 watt PEP range? Mostly plan to use on SSB but AM/CW capability would be nice also. 12 volt operation would also be nice since I travel a lot and would like to run mobile...

I plan to use a old car audo amplifer chasis.... it has an extremely effecient heat sink on it...

Hello,
Looking for 8930 tetrode in good used condition.
Commercial pull prefered. Will be used on 20 mtr band, so ok
if it's vhf capacity is a little down. Would pay $50 for unit
that still has 1 amp of peak current availible at 2kv with 300
vdc on screen. Will use for ssb so peak amps are important to me.
73 KD3SH

P.S. have lots of good (like new 4X150A) tetrodes for sale.
glass only, no later version ceramic base.

First: If everyone is patient, I'll go over every bit of this point by point in detail, and Rich can speak for himself. No one will learn anything if this becomes a political discussion or an emotional discussion of personalities.

Second: This should be about how circuits really work, and how accurate, reasonable, and logical our views are, not about people or groups. If there are 15 or 20 comments and questions at once in various areas, nothing will be addressed properly.

Finally:

While I appreciate any support (as I'm sure Rich does), I don't need or want a cheering squad turning this into a personality debate. There never has been anything personal at all in this so far as I'm concerned. It's simply a matter of technical accuracy and logical analysis.

The technical facts will ALL become absolutely clear if we are given enough time to work through this, and we all confine ourselves to one area at a time. The proper place for talking about personal opinions is rec.radio.policy.

This system is slow at times, so give me time to respond.

Hi Jeff,

I've really been wanting to talk openly with Rich about this, so I want to keep that going. Your questions relate to the discussion at the moment, and might help clarify some areas.

I wrote:
>>In any event, resonance in the anode does not guarantee oscillation.
>>The grid must also be resonant at or near the same frequency, and the
>>feedback path loss must be less than the overall gain of the system at
>>the frequency of oscillation.

And Jeff asked:
>Does the grid really need to be resonant too? Certainly, the feedback
>path loss must be less than the overall gain (and proper phase shift
>too), but as long as this second condition is met, is grid resonance
>really required?

The grid only has to have a high enough impedance to allow feedback, but the impedance peaks rapidly near resonance. So the oscillation does not have to be on the resonant frequency of the grid or anode circuit, but it does need to be somewhat near those frequencies. Understand this includes the effects of external leads.

This is why proper PA construction dictates short grid and anode leads to the point of VHF bypassing. This moves the tendency to oscillate higher in frequency, where gain is less. Any stage is easier to stabilize when the desired operating frequency is far removed from the frequency of unwanted feedback.

That's why tubes with short wide internal leads, like the 8877, are almost totally guranteed to not oscillate with any suppression in a good layout, while tubes like the 572B require a suppressor with many turns.

>How is the FCC testing performed? Is it with a nominal load (50 ohms
>resistive)? Or are there a suite of "standard" load impedances, both
>resistive and reactive, that you test with. And do you pick one
>frequency per band for testing? Sweep through? (Unfortunately, my FCC
>books are at work. What are the appropriate regs?)

The FCC is a bit off subject, and the test proceedure isn't specified anyway.

When I test a PA, I unload the input and output. I have a relay controlled line stretcher that I use to rotate the VSWR around on the input, while the output is tuned (with a pi-net output rotating the tune and load through various combinations has the same effect, with solid state I use a

line stretcher there also).

>Part of the reason why I ask is because of the damped transients that
>Mr. Measures claims he saw when testing with pulsed drive, which seem
>to be a sign that something is perhaps on the edge of stability. Under
>different loading conditions, or with a "pulse" of energy (caused by
>harmonics, distortion (creating out-of-band energy), or who knows what)
>at just the wrong frequency, perhaps sustainable oscillations could
>occur.

I think I covered how an oscillator works well enough. If a circuit is on the "edge" of stability, as claimed, then it would be a simple matter to push it over the edge. Anything we do to rasise the impedance of the anode and grid will cause a large change in feedback. I've yet to see a stage anywher close to oscillating that couldn't be made to oscillate steadily.

Let me give an example of unstable amplifiers, the Dentrons with 4- 572B tubes. Under normal loading, they are stable on 15 and ten. If the load or source is removed, and the loading capacitor is closed and the plate capacitor and tank brought to resonance near or above 25 MHz, the PA will oscillate. Yet with pulsed drive into a load, no effect of "damped oscillations" are evident. The PA is operating close to the self-neutralizing frequency of the 572's, yet if the anode is loaded heavily enough ther is no sign of instability.

>It seems as though part of the argument now is over the existance of
>destructive parasitic oscillations. Or, looking at it another way, the
>existance of the following four cases...
snip
>From the above 4, we can toss out the last as false. Now, do parasitic
>oscillations occur and, if so, can they destroy amps?

It's always nice to have one thing we can blame as the cause for every problem that occurs. We like that in life. Of course parasitic oscillations can occur if the PA isn't properly designed, or has a defective component that affects stability.

>Or are amp
>failures caused by other mechanisms. If so, what?

Of course most failures are due to other things. Many tube failures are due to manufacturing or material defects and many to poor operating habits. Poor design can contribute to or cause failures also.

>The claim that the parasitic surpressors (which are designed to stop
>these oscillations) have cured flakey amps (if true), is to me pretty
>compelling evidence that item 1 is true. If there were no parasitic
>oscillations, then how could these surpressors fix the problem?

This is where emotion confilcts with science. Let's assume you found a defective 3-500Z tube, and you assumed a parasitic caused it to fail. The tube is replaced and tricks added to "improve" stability. The PA works again.

How did you know the cure was do to the "improvement", or that the tube just had a material or assembly problem? I could have sold you snake oyl to spread on the chassis, and you'd have come away with the same opinion.

This is the very reason copper bracelets still sell for arthritis, and why people believe in astrology. The effect is emotional, rather than documented fact.

I find it fascinating that people are so unwilling to believe that sometimes tubes simply fail because they have an internal flaw. Especially when, at some times, fully 80% of a batch of tubes might be defective due to a material problem. No one used to think twice about replacing 30% of the low power, low stress tubes in a TV set once every year or two, but suddenly ANY tube failure in a PA is due to one single cause.

Not only that, parasitics are vilified as a cause of every bandswitch, tank capacitor, and choke. Every arc, spark, and even the quiet long term failures are all due to them.

Yet the designs often show no signs of instability during tests of hundreds of units, and blame is laid even though service history of the product often indicates less than one percent have the same failure after years of service.

But let's drop the speculation and move back to how things work and why things fail. With proper discussion of cicuit operation, the true problems will become very evident.
None of this stuff is magic or esoteric, it's all science.

Hi,
I want to change over a D104 Mike but I have not got a
complete manual with schematics yet. I am looking for a confirmation
to the pinout I think is right.

H goes to ground on the mike
F gets swithed at the mike to H on engaging the ptt on the D104.
C gets audio out.

The opposite side of the microphone which is connected to C goes
to ground at the mike.

Does this seem right?

> and loading must always be considered.

Yeah! An integrated-circuit designer steps into the fray! Ed, thanks very much, you hit the nail on the head. As you showed, the maximum voltage gain which can be acheived with only one transistor must be just Va/Vt or 39.5 Va (at 20 deg C), no matter what the circuit configuration (short of using a transformer)!!!

It's too bad most of the transistors in popular use by the rest of us come without a Va spec. I notice that the SPICE models of typical transistors have lower Early voltages, say 74V for a 2N2222, see the model at http://howard.engr.siu.edu/elec/faculty/etienne/spice.overview.html#Bipolar

That would imply a maximum gain of only 2900.

Of course, as you mentioned, there's always the cascode circuit to rescue things! And other circuit configurations, such as the classic 741-style opamp. With most of the voltage gain achieved in a single stage (to help insure a

single-pole response), the Va/Vt limit problem was solved by feeding the CE transistor with a current-sourced signal.

snip...

> Part of the reason why I ask is because of the damped transients that
> Mr. Measures claims he saw when testing with pulsed drive, which seem
> to be a sign that something is perhaps on the edge of stability. ... ...

Even a stable amplifier produces internal, weak, damped wave VHF ringing, Jeff. Here's why:
An L/C resonant circuit is like a bell. Strike a bell with a hammer and it rings, producing a damped wave oscillation. Shock excite an L/C resonant circuit. with a current pulse and it rings, very much like a bell, producing a damped wave oscillation. The magnitude of the ringing-voltage is proportional to the Q of the L/C circuit. Therefore, Q is probably an important consideration when designing an oscillation suppressor/dampening device.

It is not possible to construct an HF amplifier without creating a VHF resonance in the anode circuit. The anode has C. The conductors from the anode to the HF tank circuit have L. The tune capacitor completes the circuit. (The VHF resonant frequency in the anode-circuits of 1500W amplifiers varies from roughly 80MHz. to 150MHz.) Therefore, even a stable amplifier would exhibit damped-wave VHF transients in its VHF-resonant anode circui whenever the DC anode-current suddenly increased or decreased. // To view a diagram showing the VHF resonant circuits in an HF amplifier, see Figure 13 at:
http://www.vcnet.com/measures/

The interesting thing about VHF damped-wave oscillations in the anode circuit is that they can be observed with no drive signal present, merely by switching between receive and transmit modes. When an amplifier is switched from receive to transmit, or from transmit to receive, the DC anode current changes abruptly. A change in DC current is enough to cause ringing, albeit at a lower amplitude than when greater changes in anode current are used. There is no RFI problem because the weak, VHF ringing signal can not pass through the HF tank and reach the antenna. A problem only occurs when the weak ringing signal happens to get amplified, fed back, re-amplified, on and on. Bang! I don't have a clue as to what phase, current, and voltage relationships between the input and output signals are required to cause a full blown parasitic oscillation to take place. Full blown parasitic oscillations typically take place only rarely.

The magnitude of the damped-wave VHF signal is weak. The best way to observe it is to solder a half-watt 51 ohm resistor across the end of some sub-minature coax. Connect the other end of the coax to a spectrum analyzer and have a look. Keep in mind that VHF damped-wave ringing is NOT a VHF parasitic oscillation.

> The claim that the parasitic surpressors (which are designed to stop

> the surpressors somehow affect in a completely unexpected way?
>
I have never said that lowering the Q of a parasitic suppressor will Stop parasitic oscillations forever. It has been my experience, and the experience of others, that parasitic oscillations are less likely to occur with lower Q suppressors. When lower Q suppressors are combined with suitable glitch-protection diodes and resistors, if perchance a parasite appears, damage is usually limited to cheap diodes and resistors instead of uncheap tubes and meters.

Maybe some of the people who have installed lower Q suppressors should be polled to see what their experiences are?

I do not agree that anode voltage has anything significant to do with grid
dissipation.

> In a grounded grid amplifier, with the anode mistuned, negative feedback
> is removed and both the duty cycle of the grid and grid to cathode voltage
> (and hence current) increases.

HELLO, TOM. Oscillations occur in amplifiers that have previously been
tuned correctly.

When the anode (tank) is mistuned, negative-feedback is reduced, but not
removed like throwing a switch. However, the negative-feedback is only at
the operating frequency. Are amplifiers oscillating at the operating
frequency? // The problem is that at the VHF ringing frequency of the
anode resonant circuit---it's POSITIVE-FEEDBACK, an essential ingredient
for oscillation. .

In article <measures-ya023180003110960903440001@news.west.net>,
measures@mail.vcnet.com (R.L. Measures) writes:

>Question: Am I talking about arcing the fixed-capacitors or arcing the
>contacts?

Yes, you said the contacts. My mistake.

In any event, the most simple calculation would be the voltage across the shunt C of the plate tuning cap. We could easily calculate the amount of VHF current required to produce that voltage.

Correct me if I'm wrong, but you say a VHF or UHF signal can cause all sorts of current (and hence voltage) to appear across the low reactance of the capacitor, and yet claim the HF signal current, appearing across a much higher reactance, can NOT cause this voltage to appear.

That is a direct conflict with circuit theory. The HF circuit, optimized for gain at HF and with minimal impedance between the source and the capacitor under question, is expected to produce less voltage across a higher reactance than a VHF or UHF signal would across a much lower reactance.

Another conflict with fact is the claim gold can't be damaged by HF signals, but can be damaged by VHF or UHF signals, and this is somehow due to skin effect. Yet the grid is not heated by current flow through the element, it's heated by the kinetic energy of electrons smacking the outer layer of metal, the gold.

To support that claim, the high boiling point of gold is mentioned and an implication made the gold is hard to damage. Yet gold is a soft metal with a low melting point, especially when compared to the tungsten grid base material with three times gold's melting point.

Even if parasitics of the violent nature described by you could occur (which I highly doubt) this theory has two insurmountable flaws:

1.) RF is not even required to damage the outer layer first. Even dc heats the skin only since the heating effect is almost entirely from kinetic energy of electrons smashing into the grid, not I^2 R losses in the grid.

2.) Gold melts at a much lower temperature than tungsten. Even if the grid was heated evenly the gold would be damaged long before the tungsten grid showed damage.

This brings me to the point out the first harmful suggestion in your articles. You suggest the user remove electronic grid protection circuits and replace them with resistors or fuses, and claim mistuning or excessive

drive can not hurt the grid. Another claim is adding nichrome will cure grid damage.

Yet the facts indicate both excessive drive and improper tuning can cause damaging grid dissipation. Any excess grid dissipation **always** damages the gold first.

Removing an electronic grid protection circuit, as you suggested, and replacing it with someting as unreliable and slow as a fuse..or worse yet your suggestion of using a resistor, will almost guarantee eventual grid damage from over dissipation in tubes like the 8877, 3CX800A7, and so on. This is the first of several modifications that actually increase the likelyhood of tube or related component damage.

All focused beam metal oxide cathode grounded grid tubes require fast **electronic** grid overload protection. Any suggestion such circuits be removed, or manufacturer NOT including electronic grid protection, is doing so contrary to good engineering, simple facts, and common sense.

Unless the goal is to ruin expensive tubes.

Greetings from Oz

Has anyone any experience of AM transmitters using PWM of a solid state power amp? I understand that most broadcast AM transmitters use this technique nowadays. I intend to do this using a power FET switching the collector/drain volts of the RF amplifier. Are there any special problems with this approach? The PWM would work at about 100 KHz so obviously a LPF would be necessary in the supply line following the switching FET. Ultimately the idea is to apply this to a linear SSB amp. The low level signal is limited and applied to the final amp in class C while the amplitude info is "stripped off" and modulates the final as above. No doubt this has been done before - does anyone have info re best circuits and the sort of performance (efficiency/IMD) that could be expected?
Thanks in advance

Yes I'd say it counts. That's good. Sort of a very-high gain tuned
amplifier! But now we see, thanks to Ed Mullin's postings, that the
ultimate limit is surely going to be set by the transistor's output
resistance, r_o which is characterised by IC designers with the Early
voltage paramter, Va.

I am looking for a 2m xmitter implementation of the MC145170.

The MC145170 is a PLL frequency synth that also has a serial interface for interfacing with a MCU. The MC145170-1 version will go up to 185MHz.

Anyone have anything using the MC145170?

The Motorola web page has both data sheets and app notes with
enough info to roll your own. Mini-Circuits makes a VCO that
would probably perform well as the companion oscillator.

Source record: 101156

Hi,

I have a couple of new nuvistors:

QTY. Description

5 7586 RCA Made in USA, New in RCA individual boxes and they are in a
box-of-five package.

2 7587 RCA Made in USA, New in boxes.

2 7895 RCA Made in USA, New in boxes.

I inherited them and don't know what they are for. I'm not an EE.
I hope I post them in a right group. I did search for nuvistor and 7586
and found a couple newsgroups, inc. this one.
I know their new and used price (Newark and newsgroups info).
I'm selling them as is.

Please make a reasonable offer for all of them.

thanks,

robi@u.washington.edu

No it doesn't! The current source transistor provides a high impedance AND alot of DC current. The Thevenin equivalent of this source is a high value resistor driven by a VERY high voltage. The voltage is what gives you the voltage gain. Really!

The current in the emitter diode is about Vin x Ic /.025. The voltage out is this qty. times Rout. The gain is Vout/Vin which is Ic x Rout/ .025. And note that Ic x Rout is the voltage across the load resistor. When you fiddle with Rout you change the voltage across it or the collector current. You are cheating when you add another transistor which gives lots of DC current AND a high Z as explained above. The gain is "about" 39 times the voltage or "equivalent" voltage across the collector resistor up to gains of many thousands.

>

Here is where I step in it! Does the current source get around the Va/Vt limit or simply give a Thevenin equivilant with a high voltage and large resistance (and thus more gain)? I hope the latter since I just posted that theory elsewhere!

Superregens do oscillate. The break into brief oscillations at a "quench" frequency, usually above audio. The input signal modifies the rate of this oscillation (or its duration in external quench types) and hence the amount of power consumed by the circuit. Perhaps regen receivers?

....
> 73, Bill W7LZP
> wrt@eskimo.com

What you are missing is this: Suppose your supply
voltage is Vcc, and you biased the collector at Vcc/2.
So DC collector current is then Ic=Vcc/2Rc where Rc is the
collector resistor.

Now small signal transconductance, gm of the transistor is:
gm=q Ic/kT, so if the voltage applied to base is v1, the change
in the collector current is :

ic= gm v1

and

collector voltage vc :

vc= - Rc ic or if you combine all the eqs. above

vc= -Rc q Ic/kT v1

now if you replace Ic with Vcc/2Rc, the output voltage becomes
independent of Rc!

vc=-q Vcc/2kT v1, or the gain is: -q Vcc/2kT! no collector
resistor dependence...

THIS IS THE FAIREST MOST HONEST WAY I KNOW TO

SHARE THE WEALTH! Hi there!

Question: would you like to make thousands of dollars,

quick, legally, with NO CATCH? If Yes, then keep reading. Please

take five minutes to read this article. It will change your life, just

like it did mine. If you're not interested, I apologize for wasting your

time.

It's true! You can make up to or over $50,000 dollars in 4-6

weeks, maybe sooner! I SWEAR I'M NOT LYING TO YOU, AND

THIS IS NOT A SCAM! Interested? Then here we go.

A little while back, I was browsing through these

newsgroups, just like you are now, and came across an article

similar to this one, which said; "You could make thousands of

dollars in weeks with an initial investment of only $5!" So, I thought,

"Yeah, right, must be a scam!"... ...but like most of us I was

curious. So, I kept reading.

It said you send $1 to each of the 5 names and addresses stated in

the article. You then place your own name and address in the

article at the bottom of the list at #5, and post the article in at least

200 newsgroups (there are thousands). No catch, that was it!

So I thought it over, talked to a couple of people about the

whole thing. I figured what have I got to lose except for 5

stamps and $5? So, I tried it.

Well, guess what...within 7 days, I started getting money in

the mail! I was shocked! I figured it would end soon, and didn't

give it another thought. But the money kept coming IN, tripling in size and multiplying by 10-20 times the amount that I got the first week! In my first week I made a total of over $1,000!!!! In the third week, I had over $10,000 dollars, and it's still growing. This is my fourth week (Oct 28) and I've made about $42,000 TOTAL, and the money is still coming in.....

Let me tell you how this works and more importantly, WHY it works. Make sure you print a copy of this article NOW, so you can use the information from it, and begin making money.

The process is very simple, and it consists of 3 EASY steps:

STEP 1: Get 5 pieces of paper and write the following on each sheet of paper..."PLEASE PUT ME ON YOUR MAILING LIST." Fold each piece of paper in half. Take five $1 bills and place ONE in each piece of paper. Then put each piece of paper in to it's own envelope and seal it. You should now have 5 sealed envelopes , EACH containing a piece of paper AND a $1 bill inside the folded paper. Make sure the words ..."PLEASE PUT ME ON YOUR MAILING LIST." are written on each piece paper. By doing that, you are creating a service and it's PERFECTLY LEGAL.

Finally, mail 1 envelope to 1 of the following 5 addresses:

1. S. Shaw, 611 23rd St., Sacramento, CA 95816
2. G.Charters,5809 Hudson St., Vancouver, B.C. Canada V6M 2Z2
3. D.Miller, 26 Aristone Dr., Berlin, NJ 08009
4. B.Peale, 1619 Nth 5th St., Perkasie, PA 18944
5. D.Watson, 2430 W.Territorial Rd., Battle Creek, MI 49015

STEP 2: Now take the #1 name off the list that you see above, move the other 4 names up (5 becoming 4, 4 becoming 3, etc..) and put YOUR NAME as number 5 on the list.

STEP 3: Post your amended article (with you name at #5)
to at least 200 news groups (I think there are close to 18,000 of them). This is easy to do. You can either type out this message (altering any part you deem worthy, EXCEPT the name and addresses) with an ordinary editor or with your web browser's 'To:News' key at the upper left corner of this screen (Netscape Navigator 3.0). After typing this article, save a copy. Any time you want to post this article on a newsgroup, just use a flashy subject and post your saved copy. That's it, easy! Now, post the message to at least 200 DIFFERENT newsgroups. 200 IS THE MINIMUM. The more you post, the more money you will make. You are now in the mail order business and will start receiving your $1 envelopes from various people all over the world within days.

HINT: THE MORE NEWSGROUPS YOU POST TO, THE MORE MONEY YOU WILL MAKE. You may even want to rent a PO Box, eventually because of all the mail. If you wish to stay anonymous, you can come up with a name, such as "manager" or "investor." Please be sure to check that all the addresses on the envelopes are correct.

.

LET ME TELL YOU WHY THIS SYSTEM WORKS!!!

Out of every 200 postings, let's say I ONLY receive 5 replies, which is actually VERY LOW. So I made 5 dollars with my #5. Now then, each person who just sent me $1 makes, say only 200 POSTINGS, now with your name at number 4, WHICH IS A TOTAL OF 1000 POSTINGS, not including yours too. 50 people send you $1 now; that's $50 you just made! Now, then your new 50 agents post 200 each with YOUR NAME AT NUMBER 3, OR 10,000 POSTING (50x200). Average return is 500 at $1 each is $500. They make 200 postings, which is 5,000 returns at $1 each, which

is $5,000 dollars! And finally, 5000 people make 200 postings each with YOUR NAME AT NUMBER 1. YOU NOW GET A RETURN OF $50,000 BEFORE YOUR NAME DROPS OFF THE LIST. AND THAT'S IF EVERYONE MAKES 200 POSTINGS ONLY, AND IF ONLY 5 PERSONS RESPOND!!!!!

When your name is no longer on the list, you just take the latest posting that is appearing in the newsgroups, and SEND OUT ANOTHER $5 TO THE NAMES ON THE LIST, PUTTING YOUR NAME AT 5 AGAIN. And start posting again. The thing to remember is, do you realize that THOUSANDS OF PEOPLE ALL OVER THE WORLD ARE JOINING THE INTERNET AND READING THESE ARTICLES EVERY DAY, JUST LIKE YOU ARE RIGHT NOW!!! So can you afford $5 dollars and see if it really works? I think so....

People have said, "What if the plan is played out and no sends the money?" So what! What are the chances of that happening when there are TONS OF NEW HONEST USERS AND NEW HONEST PEOLE who are joining the Internet and newsgroups everyday and are willing to give it a try?

Estimates are at 20,000 to 50,000 new users, every day, with THOUSANDS of those joining the actual Internet. Remember, play FAIRLY and HONESTLY and this WILL WORK, I PROMISE YOU!!!

Honesty is the key, and the best policy. Make sure you print this article out RIGHT NOW, also, try to keep an eye on the newsgroups to make sure everyone is playing fairly.

REMEMBER, HONESTY IS THE BEST POLICY. YOU DON'T NEED TO CHEAT THE BASIC IDEA TO MAKE MONEY!! GOOD LUCK TO ALL AND PLEASE PLAY FAIRLY AND YOU WILL REAP THE HUGE REWARDS FROM THIS, WHICH IS TONS OF EXTRA CASH!!!

<< By the way, if you try to deceive people by posting the

messages with your name on the list and not sending the money to

the people already on the list, you'd be wasting your time.

I talked to someone who did that and only made $150 dollars, and

that was AFTER seven or eight weeks! He decided to send the 5

$1 bills, and in 4-5 weeks, he had over $10K. >>

THIS IS THE FAIREST AND MOST HONEST WAY I HAVE EVER SEEN TO SHARE THE WEALTH OF THE WORLD WITHOUT COSTING ANYTHING BUT OUR TIME!!

GOOD LUCK!

A roof mounted high gain antenna, with a rotator, low loss feeder to the
receiver. A band tuned (not a broad band) amplifier can be fitted at the
mast head with just enough gain to overcome feeder loss. The noise
figure should be as low as possible, at least as good as the receiver.
This must also have good dynamic range or it will be crossmodulated by
strong local signals.

Hope this helps

>Its totally invisible to the remote test gear. If you doubt it try it!

You probably mean "measuring the impedance at the antenna feed point". If used for that purpose, even a small amount of coax loss can make a suprising amount of difference in the measurement. It's particularly bad if the impedance to be measured is very different from the Z0 of the half wavelength cable. Loss will cause the value looking into the line to be skewed toward the Z0 of the cable.

As for SWR measurement, consider an antenna which has exactly a 50 ohm feedpoint resistance and no reactance. Connect it to your rig with a half wavelength of 75 ohm cable, and put an SWR meter at the rig end. A 50 ohm SWR meter will read 1:1. The SWR on the cable is 1.5:1. A 75 ohm SWR meter, if you can find one, will read 1.5:1. (Actually, the meter will read a little less due to inevitable cable loss.)

How about an antenna which has a 75 ohm feedpoint resistance and no reactance, connected to the rig with a 50 ohm cable? A 50 ohm SWR meter at the rig will measure 1.5:1, regardless of the length of the coax. (Again, the actual reading will be a little less due to loss, and will decrease as the coax gets longer because then the loss gets greater.)

Roy Lewallen, W7EL

o.k., you want prices..so i'll assign price's to most items, or all
items are 'make reasonable offer'
all are plus shipping.
i'm not hard to deal with....we all like to get something at 'our
price' don't we? take a chance, the
worst i will do is make a counter offer....plus shipping (although,
pickup on heavy items would be
nice, but not a must)
location address & phone number, are in my sig.
****
TRADES:
I am in need of 2 - 32mb 72 pin simms 60 or 70 ns (both the same)
non-edo strips
flatbed color hi res scanner (1200 x 1200 or better)
2 meter allmode base
6 meter allmode base
Capacitance checker digital *must* be able to check air variables
range pf thru mmfd
other trade items considered...email what you have & what you want to
trade for...
**********□
P.S. if you call, and the phone is busy, it means i'm on the computer
(internet) send email
and let me know your trying to call.....(gotta get another line 8-)

>the skin only since the heating effect is almost entirely from kinetic
>energy of electrons smashing into the grid, not I^2 R losses in the grid.

Ah. What's the electron velocity in the neighborhood of the grid?
As I recall, the grid is located very close to the cathode. The relatively
small grid potential is able to modulate a large electron flow because
that little potential is able to overcome the kinetic energy of the
electrons heading for the anode.

In fact, a potential of about -100 volts seems to completely cancel
the velocity built up due to the anode potential, and cut the tube off.
Thus we're looking at electron kinetic energies in the vicinity of
the grid of less than 100 electron volts are we not? An eV is an
exceedingly tiny amount of kinetic energy.

Now down at the other end of the tube, the electron is really hauling,
and the kinetic impact *is* the major source of heating of the anode.
But down very near the cathode where the grid is located the electrons
are barely getting started accelerating. They're just loafing along.
Kinetic energy is proportional to the square of velocity, and the
electrons just aren't moving that fast right off the cathode. I'm
going to have to see some numbers before I'll buy that kinetic
energy is the primary source for heating the grid.

>2.) Gold melts at a much lower temperature than tungsten. Even if the grid
>was heated evenly the gold would be damaged long before the tungsten grid
>showed damage.

Yeah, but the plating will spall off due to core thermal expansion
long before it can melt. It won't melt and form spherical melt balls
splattered around the innards of the tube if the heating is uniform.
There'll be flakes and ribbons of gold strewn around the tube if the
heating is uniform.

>This brings me to the point out the first harmful suggestion in your
>articles. You suggest the user remove electronic grid protection circuits
>and replace them with resistors or fuses, and claim mistuning or excessive
>drive can not hurt the grid. Another claim is adding nichrome will cure
>grid damage.

Oh, oh, that does sound like bad advice.

>Yet the facts indicate both excessive drive and improper tuning can cause
>damaging grid dissipation. Any excess grid dissipation **always** damages
>the gold first.

I still don't think you've made a case for this. Excess RF dissipation
yes, excess DC dissipation, you'll have to do better if you want to
explain the melt balls.

>I think you meant to say, "...connected to the rig with 75 ohm coax."

Nope. Often as I screw up, I managed to say what I meant this time. But the 50 ohm SWR meter would also read 1.5:1 for any length of cable if the cable were 75 ohms. (Of course the SWR on the cable is 1:1 in this case, not 1.5:1 as it would be if the cable were 50 ohms.)

I corrected that, it should hve been grid to cathode voltage

Could you comment on my dissipation figures and the causes of gold damage?

>> In a grounded grid amplifier, with the anode mistuned, negative
feedback
>> is removed and both the duty cycle of the grid and grid to cathode
voltage
>> (and hence current) increases.
>
>HELLO, TOM. Oscillations occur in amplifiers that have previously been
>tuned correctly.

Hello Rich,

You said:
>When the anode (tank) is mistuned, negative-feedback is reduced, but not
>removed like throwing a switch. However, the negative-feedback is only
at
>the operating frequency.

Not at all. It affects the input and anode impedance at every frequency,
at the parasitic frequency and even dc.

I'm not sure if I wasn't clear enough. I sopke of feedback in to separate
contexts, one was when I was discussing grid damage. In that case, if
loading is reduced negative feedback is reduced. Since the input and
output are in series in a grounded grid amplifier, feedback is dependent
on the ratioo of driving impedance to output impedance. In this case,
lighter loading (higher anode impedance) causes grid current and grid
dissipation to increase. This is the primary cause of grid damage in
grounded grid focused beam power grid tube PA's, and the reason for damage
to the gold plating (low temp) of the tungsten grid (high temp). It is a
virtual certainty that improper loading (for higher drive levels) will
cause damage to the grid. Contrary to your claims the effect is kinetic
energy (the collision) from electrons hitting the outer surface of the
grid that causes heating, distributed resistance (and hence skin effect)
has no effect, since the heating is not from I^2 R losses. And contrary to
your claims the gold melts at much lower temperature (three times) than

the tungsten core grid. As I said, Eimac gives a rated grid dissipation based on the effect of electron bombardment, not I^2 R heating of the element.

Let's not mix that issue with this one:

The other case delt with any possible oscillation. If the tube started to oscillate, the anode impedance would decrease. If the oscillation caused grid current to flow, the grid impedance would drop. Feedback (regenerative in this case) would decrease. The path is this:

gnd----Anode Z-----][----grid Z---gnd

A decrease of anode Z (because it controls the source voltage) or grid Z (the load) causes a reduction in feedback, and a limitation of amplitude. So it is impossible for a stage operating below the the limits of self-oscillation, to suddenly break into uncontrolled catastrophic oscillation as you theorize.

>Are amplifiers oscillating at the operating
>frequency?

No, most likely they are not oscillating at all in the real world. They either are unstable at any hour of the day, or they are not. They don't conveniently oscillate just for one quick instant of time just to support theories. Oscillator theory isn't esoteric.

>The problem is that at the VHF ringing frequency of the
>anode resonant circuit---it's POSITIVE-FEEDBACK, an essential ingredient
>for oscillation.

Why do you say ringing is positive feedback? Feedback, by definition, has to include the path from output to input. Ringing isn't any kind of feedback, it's just an effect of resonance.

73 Tom

> That is a direct conflict with circuit theory.

Initially, I was also puzzled by the seeming ease with which a VHF
oscillation can arc over a tune capacitor with a much higher HF peak
voltage rating than is required for the amplifier. However, capacitor
plates are arcing/melting too often to ignore. One possible explanation
is that VHF and especially UHF voltage is not like 60Hz voltage. I built
a high power amplifier for 432MHz, and I experienced some UHF arcing.
UHF's ability to arc large gaps was awesome. The sound, smell, and the
purplish-red color of the UHF arc is like something out of this world.

According to aerodynamic theory, a bumblebee can not fly. However,
bumblebees in this neighborhood seem to manage a fairly good imitation.

Here's an AC theory question, Tom. Do think it is possible to take
120V/60Hz and make 10,000V/60Hz with one capacitor and one inductor?

Did I say that ringing was a kind of feedback? Did I say that ringing is
positive feedback?

The VHF ringing signal in the anode resonant circuit is fed back to the
cathode input by the anode-to-cathode feedback capacitance of the tube.
The VHF feedback is positive because the HF tuned output and HF tuned
input are not even in the picture at VHF.

Good points, Gary. The energy just isn't there from that to boil and evaporate gold. // I was looking at an 8877 grid structure this morning. My best educated guess is that it would take between 500W and 700W to raise the 8877 grid structure to a temperature of 2000 degrees..

It would be bad advice if electronic "grid protection" circuits were designed to handle the fault currents encountered during a potentially gold-sputtering event.
I get phone calls from people who have gold-sputter damaged amplifier tubes in amplifiers that have electronic "grid protection" circuits. The grid protection circuit shorts out during what I believe was a vhf parasitic oscillation--that simulataneously damaged the tubes.**
During some vhf parasitic oscillations, I know that the peak grid current is sufficient to melt the copper wire in a 1A choke. This feat probably takes a pulse of over 15a. Since most of the electronic "grid protection" circuits use a 1A to 2A output transistor, would transistor shorting seem likely from a 15a pulse? How much current limiting protection do you get from a dead-shorted transistor?
OTOH, a 15a pulse will open a 30 ohm 0.5w carbon-film resistor every time, without fail, stopping the flow of current through the grid. I received a telephone call this morning from a fellow in Reno whose had a blown grid fuse resistor, but whose new tubes were undamaged.

> explain the melt balls.
>
> Gary

I agree, Gary. I don't see how the sound and fury associated with whatever produces the gold melt balls could be caused by by some extra drive to an amplifier that was tuned up 10 minutes or so before the big event.

I have seen gold in the liquid state and it is impressively hot, glowing a bright yellow color. The gold vapour needed to make melt balls would be even hotter.

** The gold-sputtered 8874 that was shown in the photograph in the article "Parasitics Revisited" (QST, Sept./Oct. 1990) was removed from an ETO 3-holer that belonged to QST Staffer Rus Healy, NJ2L. Anybody want to venture a guess why I could NOT say that in the article?

The amplifier had another 8874 that was moderately gold-sputtered. The third 8874 was lightly gold-sputtered. The ETO electronic "grid protection" circuit was shorted. Rus Healy is no longer working for QST.
The real puzzler is that Dick Erhorn or Ray Heaton have never, to the best of my knowledge, ever tested a tube for gold-sputtering damage with a high voltage breakdown tester.

I'm using the CB band specifically which I believe is ISM band.
27.15 MHz, the medical community uses this for diathermy.

Anyway, the question is How about a matching circuit? I'll
only be using a 250 Watt amplifier but desire about 1000volts
into an Argon gas to ignite it. A faraday cage will also be used
as to NOT radiate this energy.

> - Jeff, WA6AHL

Someone has contacted Eimac, Jeff. The fly in the ointment is that the 8877 design team no longer works at Varian-Eimac. // BTW, rumor has it that Eimac sold their glass tube division to General Electric.

In February of 1986, I had a discussion with the specs engineer who worked with the 8877's engineers.. He told me that the tube engineers discovered the gold sputtering problem during the testing phase of the 8877's development. They concluded that gold sputtering from the grid plating was due to parasitic oscillations. One look through a microscope convinced me they were right.

When I spoke with an Eimac engineer in early 1991 about their warranty policy on gold-sputter damaged tubes, he told me that if even if a tube is leaky because of sputtered gold, the tube is replaced without question. He said that the people in the warranty division are not even set up to test for gold-sputtering.

The bottom-line is that at least one engineer was aware of the gold-sputtering problem in 1991.

I find it curious that the folks in the warranty division were/are clueless, and nobody seems to care. Or, maybe it's just a hold-over from the days when Eitel and McCullough owned the company, and ANY kaput tube made by Eimac was replaced without question. Truly, the customer was always right.

Is this semantic territory? I saw your "gain-comes-from-voltage" idea in this thread, and surely using thevenin equivalent circuit elements is fine, although I don't usually think of it that way when using current sources.

Wrt to the Va/Vt limit problem, I was thinking about the "Early effect," which causes most of the apparent collector output resistance in the first place. The Early effect says that Vbe for a given Ic will change a little bit if you change the collector voltage. This also means that for a constant Vbe, the collector current will change a little bit as you change collector voltage. This change can be seen as an little current flowing in a resistor loading the collector - hence r_o.

Incidentally, if r_o is defined just from the "Early voltage," Va, then r_o = Va / Ic (r_o changes with collector current) and the size of the Early effect is dVbe/dVc = Vt/Va where as usual Vt = kT/q. For the 2N2222 spice model, with Va = 74V (i.e. r_o = 74k at 1mA), this is 0.00034. I digress.

Think of a common-emitter cascode amplifier. Because the collector of the CE transistor drives the cascode emitter and doesn't experience significant voltage variation, it doesn't have an Early-effect Vbe problem. The cascode transistor doesn't have an Early-effect Vbe problem either, because its emitter input is driven by a current source. Although there will be changes in Vbe as the output swings up and down, the bulk of the current in the emitter still has to appear in the collector.

That's the "solution" to the Va/Vt limit.

I suppose it is semantics but I have seen others suggest that the gain comes from the high impedance of the current source alone. But a current source would run into the same gain limit as an equal value resistor if it weren't for the higher DC current. The Thevenin equivalent description just seems irresistably simple. I'm not sure that the current source gets around r_o but rather lets you approach it (gain of 39 x Va) with a reasonable collector current.

The cascode circuit is a different matter!

2502. Re: Good source for amplifier tips

Source record: 101185

Guys,

[Interrestion discussion about stability snipped]

"OK, I'll bite...", said Bob, leading with the chin...

First thought. With transistor amplifiers one can verify by modelling and Linville stability curves (spelled wrong I'm sure) whether an amplifier is unconditionally or only conditionally stable. Do models of these tubes exist? Can the stability be analyzed/proved? I think I've seen spice models for receiving tubes.

Second thought. I've never designed a tube power amplifier but I have some experience designing with CRT tubes. CRT tubes arc over on occasion. In an effort to improve the robustness of an problematic airborne CRT display we decided to make measurements of a CRT arc in process. We used a pulsed welding laser aimed at the electrodes inside the neck of the tube to facilitate an arc. When we fired the laser, we would create a conductive plasma from the vaporized electrode metal and an arc would ensue. One thing that became evident is that the di/dt from an arc in a vacuum is much higher than the di/dt from an arc in air. Indeed sub nanosecond current risetimes were observed. VHF ringing was also observed in the anode wiring. Just wondering if this could explain VHF excitation
of the output network.

>rectanglular grid wires face the cathode, so heat transfer is minimal.
>Another factor is that gold is excellent for not absorbing infrared
>radiation.

Hi Rich,

There seems to be another basic problem with the gold theory you offer.
You seem to thing the gold has to boil for material to be lost, but that
is totally untrue.

Materials have a bonding action that keeps them from falling apart, but if
any individual atom has an energy level that exceeds the bonding potential
an atom can leave the lattice or its' neighbors. This occurs in a solid,
as well as a liquid. Water doesn't simply sit there and not evaporate
until it boils, and neither does gold.

The energy of the electrons striking the grid is expressed in volts, and
the number of them striking the grid is expressed in amperes. When the
electron stikes the gold, it has to impart its energy on the gold, aand
that raises the energy level of the particular atom it strikes. If the
increase in energy level is sufficent the atom will "evaporate" from the
surface, even if the rest of the surface is very cold.

Why is it so surprising the material on the grid eventually deteriorates
over time and migrates to other areas of the tube, or that short term
heating accelerates this process and damages the tube? Why is it OK for
this to happen in the cathode (without the materials in it "boiling" or
even becoming a liquid) and not in the grid?

As a matter of fact, the cathode life of a MOX cathode power grid is
primarily a function of filament hours at a given temperature UNLESS a
safe emission reserve margin is exceeded. A thoriated tungsten tube is
strictly a function of filament hours and temperature and are not damaged
by emission saturation. Material from the filaments and cathodes slowly
vanish, yet by the "rules and explainations" you offered for the grid this
shouldn't happen... unless we boil the cathode.

I'm puzzled at the large difference between known published physics and
science and your theories. For example, the quantum energy of a photon
must be billions of times larger than they tell us for the effect you
describe in a tube from photon bombardment to occur. Are hundreds or
thousands of reference textbook (dealing with physics and electronics
theory) authors involved in a sinister plot to mislead us all?

The output and input shunt reactances are very much in the picture at VHF.
Use your calculator, or borrow an RF impedance meter.

If you pick a frequency, I'll measure the phase shift and loss in the
feedback path. We can calculate the tubes gain under the best condition.
Or better yet, do the experiment along with me.

For Gary, KE4ZV

Don't overcomplicate grid dissipation Gary. It's given simply as the voltage times current at any given instant of time, and the resulting average value of dissipation over time. I explained the calculation. It is approximated by taking the average voltage grid to cathode voltage over the portion of the cycle when the grid is positive compared to the cathode (you can use a polarity sensitive and dc biased RMS RF voltmeter to measure this), and the average current (which is measured for you on the meter).

In a grounded grid amplifier, with the anode mistuned, negative feedback is removed and both the duty cycle of the grid and grid to cathode voltage (and hence current) increases.

At 150 mA of grid current in a typical HF PA, a single 3CX800 has a measured grid dissipation of almost 20 watts. That's almost 5 times the maximum rated dissipation of the grid.

And yes, it will cause the gold to ball up, evaporate and even flake off. And yes, Eimac will confirm this.

In article <measures-ya023180000211961056110001@news.west.net>, measures@mail.vcnet.com (R.L. Measures) writes:

> After the first article I wrote about vhf parasitics was published in *Ham

>allegedly having taken place when the amplifier was sitting quietly with
>the tube cut off. I asked many people about this phenomenon. There was
>only one scientificly-based explanation we could come up with. (Someone
>suggested that any amplifier that exhibits occasional arcing on standby,
>can only be cured by an exorcism.)

Now the amplifier will oscillate with the tube cut off. Here come the things from outer space that turn the PA on by themselves.

Never mind the poor guy had a gassy tube, it still has to be explained as a parasitic! This time the evidence is a Geiger-Muller tube clicks. Unfortunately Rich:

1.) The Geiger-Muller tube must be filled with gas (argon and ethyl alcohol) or it won't "tic"

2.) When it does "tic" the current is 5x10-14th amp for ten particals per second with each particle loosing 1 MeV.

3.) The "tic" is ion movement, not electrons. The tic is from a current of less than a pico-ampere.

Rich, how many 1000v relay contacts do you think would arc from a current of .00000000000005 amperes? How long does it take .00000000000005 amperes to charge up all the .01 caps (two to the input circuit, two to ground for a total of .04 uF) enough to allow the relay to arc over? How many photons are required to cause that current in a near perfect vacuum? Is a 3-500Z tube filled with argon and ethyl alcohol?
Do people have atomic reactors in the PA? Perhaps a dose of >10000 rems for a few seconds would make the relay arc if the tube was gassy, but the operator wouldn't care. He'd die anyway.

Why don't photons from the normal electromagnetic energy in the tube cause it to arc?

If you can overcome these problems, you may have finally hit on a true theory.

Hi, Tom. I hear you are in conversation with Rich Measures.
To answer your question regarding the 3CX800A7, this tube uses a grid made
from material which has a high melting point (Molybdenum or Tungsten)
plated with gold. If one over drives this tube or operates it at high
grid current due to improper loading or failure in the matching network or
load, then it is likely that the temperature of the grid will quickly,
within seconds, become high enough to vaporize the gold. This may be what
happened to the 8874 tubes that Measures returned to Eimac a long time
back and Bill Foote, then responsible for writing letters related to
returned products, wrote something about a microwave oscillation that we
saw IN ANOTHER PRODUCT, maybe he did not make that distinction, but to
this day Measures believes that the incidence of failures with gold
evaporated from grids are entirely due to parasitic oscillations, and
tries to hold this letter from Mr. Foote as evidence. This is bunk. I
trust that is what you are discussing with Measures? May I suggest that
you make your life more enjoyable, do something else than arguing with
Measures.

In article <measures-0211960255270001@port15.vcnet.com>,
measures@mail.vcnet.com (R. L. Measures) writes:

>Initially, I was also puzzled by the seeming ease with which a VHF
>oscillation can arc over a tune capacitor with a much higher HF peak
>voltage rating than is required for the amplifier.

That's another mistake. You seem to think the peak anode voltage can only
be 2Ep, but that is totally untrue. The peak HF anode voltage can be much
greater than 2Ep.

>However, capacitor
>plates are arcing/melting too often to ignore. One possible explanation
>is that VHF and especially UHF voltage is not like 60Hz voltage.

How did we get to 60 Hz?

Rich, you never answered or commented about the fact we just have a simple
pi network between the tube and the tank input. We can look at that
circuit with simple test equipment and end all the guessing. Let's take a
typical case of a production AL-80B.

I just coupled a constant voltage signal to the AL-80B 3-500Z anode, and
here's what I measured (the band switch was set to 20, but it made no
almost difference in readings above 35 MHz what band the tank was set
for). The voltage at the anode was 800 mV. The readings are described as
mn=min obtained , r= 20 mtr resonant point, mx= maximum obtained as the
tuning cap is rotated through it's range. Voltages are measured across the
tank cap. Values are in mV.

500 MHz 12 for all settings
400 MHz 14 for all settings
300 MHz 22 for all settings
200 MHz 45 for all settings
175 MHz ~60 for all settings
150 MHz 85 mx, 6 mn, 32 r
140 MHz 15 mx, 5 mn, 5 r
130 MHz 80 mx, 3 mn, 3 r (resonant point of grid)
120 MHz 33 mx, 14 mn, 18 r
110 MHz 34 mx, 2 mn, 17 r
100 MHz 130 mx, .2 mn, 30 r (resonant point of anode)
90 MHz 140 mx, 1.5 mn, 35 r
80 MHz 210 mx, 10 mn, 70 r
70 MHz 280 mx, 15 mn, 70 r
60 MHz 400 mx, 18 mn, 73 r
50 MHz 500 mx, 19 mn, 74 r

The voltage increases at a linear rate until at 20 MHz it reaches 800 mV max.

I wonder if you could explain how a VHF or UHF signal at the anode could cause the capacitor to arc, since the voltage step down is about 25 to one at the resonant frequency? Can the anode and plate choke withstand 87.5 kilovolts?

By the way, the bandswitch voltage was lower yet, about 30% lower.

>Here's an AC theory question, Tom. Do think it is possible to take >120V/60Hz and make 10,000V/60Hz with one capacitor and one inductor?

Absolutely, if the Q is high enough, the components are in the right positions, and they have the correct value. Now here's a question for you. Do you suppose they would make 10,000 volts if the circuit was like this:

source-- - shunt 100 ohms ---L series 100 ohms in shunt with 218 ohms r---- -shunt 32 ohms--output

Do you think we would get 5 KV at the output if we applied 5 kV at the source? 10 kV?

The "parasitics cause the tuning cap to arc" is just another wild claim that holds no technical merit at all when the facts are examined, just like the gold on the grid.

It does not seem to be just a theory, Tom. I took a look at a
gold-sputtered grid through a microscope. It could see that gold had
bubbled and evaporated. The plethora of gold melt balls I saw on the
cathode could only have been formed from condensed gold vapour.

I do not deserve credit for the vhf-uhf-parasitic/gold-sputtering
theory. It originated at Eimac. I am only the messenger.

I've never received a satisfactory explanation of why such events happen but I don't get the feeling that it is related to background radiation. If it matters, this particular display was surrounded by a pretty substantial mu-metal shield. The only consensus I got from our experts was that these events "just happen". "You might as well design the electronics to withstand them." Oh well...

Hi gang;
well it's been hecktic the last few days, the father-in-law in
hospital
agin this year, last had his left lung removed, this year his right
kidney...
touch & go...wife in a turmoil...
ANYWAY, the list i posted here, is doing good,
but, Remember.....this is stuff i don't want/need....make offers..
there is a small list of items i'd trade for included, although it's
not the only stuff i'd trade for......this suff takes up a lot of
room/space....it wouldn't hurt my feelings if someone took it
all...(that would be a pick-up for sure)
IF you think a price is out of line...think " I'll make an
OFFER"
as long as it's a reasonable....you can't insult me....
thanks for the space, if you want the list again, or would
like it for the first time, email me.....remember it's parts &
some equipment..etc.

thank you

>suppressor/dampening device.

That's not entirely true. In a tank, as in a Bell, the peak voltage
developed during the ringing can not exceed the level of the single pulse
that drove the Bell.

The effect is very much like a pendulum, one perfect tug and at the very
most the voltage equals the voltage delta of the tug.

If the tube "pulls" the voltage low in step with the resonant frequency
over and over again, and losses do not exceed the energy supplied by this
"pull", voltage can build up. It builds (and as it does losses also
increase) until equilibrium is reached between energy applied and energy
lost.

In no case is the bell or tank an amplifier or multiplier of energy,
although it is a simple energy storage system.

>A change in DC current is enough to cause

>signals are required to cause a full blown parasitic oscillation to take
>place. Full blown parasitic oscillations typically take place only
>rarely.

This is where the theory falls apart (just as the gold migration
explaination did), here's why.

If the stage has enough feedback to sustain oscillation, it will start on it's own. Gain of any tube is highest when the anode impedance (E/I) is highest, and the grid impedance is highest (E/I). As soon as any tube has the plate current or grid current increase, gain drops. (You can confirm this on your PA at home by driving the PA with low power, tuning for maximum power, and measuring the gain. If you apply more power, tune for maximum power, and measure the gain, it will be less.)

When a stage oscillates and causes grid current or increased anode current, gain decreases. When the stage is driven with fundamental RF, gain decreases.

>I have never said that lowering the Q of a parasitic suppressor will Stop
>parasitic oscillations forever. It has been my experience, and the
>experience of others, that parasitic oscillations are less likely to
occur
>with lower Q suppressors. When lower Q suppressors are combined with
>suitable glitch-protection diodes and resistors, if perchance a parasite
>appears, damage is usually limited to cheap diodes and resistors instead
>of uncheap tubes and meters.

The giant leap from dampened ringing (which really is a simple frequency response peak) to damaged meters and diodes is hard to understand. So far, nothing has indicated the suspected violent oscillations occur or even could occur, and every bit of damage described can have multiple cuses not related to parasitics.

It sounds like we are grasping at straws to blame every single problem from meters to tubes on something we can't see or measure, rarely occurs, and makes little technical sense when analyzed.

I'd like an explaination of HOW a VHF signal can produce many kilovolts across the low reactance of the tuning cap, while lower frequency signals (where the reactance is higher) can't. How the system can operate happily for days or years without a failure, and suddenly go unstable. How the gold can be damaged only by a very brief VHF signal, when the heating is not even related to skin effect.

We haven't even done that, and now we've added the meters and diodes to the components damaged by parasitics. Hopefully if the plug falls out of the wall it won't be from a parasitic.

> The cascode circuit is a different matter!

Of course, current sources also have an Early-effect-induced r_o problem which limits the gain. In the case of a simple pnp transistor current mirror, as often seen in ICs, the effect can be severe. Remember Ed Mullins mentioned a typical bipolar IC process with Va of 20V for pnp compared to 200V for npn devices. Using a cascode pnp current source would be a solution, and I've seen it in some circuits, but the Wilson current mirror (AoE fig 2.48) also reduces the effect of Vbe variation with collector voltage, providing a greatly increased output resistance.

Fools rush in...

Gentlemen: Regarding the temperature rise in the grid structure, have you considered that the grid is very near the cathode and is running at an elevated temperature even without additional dissipation.

Mind you, I don't have a clue as to the actual spacing or the cathode temperature in this tube. Just asking.

Hello to all:

Looking for some information--

Am trying to bring back to life an old Heath SB-303 for station at
children's school.

Several have helped with info.

Does anyone have tube substitution information for the following two
tubes?

6AU6
and a 6EA6

I have a small box of tubes scrounged from other radios that were too far
gone to repair for club.

I used to have the GE substitution book but it has gone elsewhere

Thanks for info
tnx and 73, DAn

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-03 00:00:00 UTC
From: tswisher@freenet.columbus.oh.us
Message-ID: <55j4td$kbo@login.freenet.columbus.oh.us>
Source record: 101113

Hello all;

I've got a Yaesu FT-73 that, like it's newer siblings, uses "add/remove Jumper" type modifications to alter various aspects of the operation of the radio. This particular unit has been modified so that the display shows "CH 1" "CH2" "CH 3" and so on for memory channels, as would be found on the commercial "Vertex" version of the FT-73, rather than the frequency in the main window and the channel number in the upper left corner of the display, as is normally found on the amateur version FT-73.

Does anyone out there have a list of the various jumper assignments for the FT-73? I'd like to restore the display to it's proper state for amateur use.

Thanks,

Tom Swisher, N8GQK

Fortunately all the participants do agree that we're looking for
something more substantial than that: we're looking for a scientific
explanation that fits all the facts.

Standing on the sidelines and sorting through the evidence, here's what
it seems to say to me, so far, FWIW.

>Geiger tube, does it seem possible that high energy photons could create
>current carriers by strinking atoms within an amplifier tube?

I don't think so; and ionizing radiation is something I do know about. Cosmic rays are passing through you, me and your PA tube at quite a frequent rate, leaving small trails of separated electrons and positive ions. Some of the electrons are energetic enough to create additional electrons (secondary ionization) but most do not, so the overall effect is usually that the trails of ionization recombine with very little long-term effect. A Geiger tube is specially built to maximize the effects of secondary electron multiplication, so that each ionized trail creates a much larger shower of secondary electrons that is big enough to register as a pulse. The conditions to achieve electron multiplication are quite specific: the tube is filled with an ionizable gas at a critically optimized pressure.

Such conditions do not exist in a normal vacuum tube. If there is a transient effect that sends the tube into violent conduction, it's much more likely to be due to a release of a micro-pocket of trapped gas, or a flake of material falling off one of the electrodes. It doesn't seem to be necessary to invoke cosmic rays to explain this.

>If this is
>possible, then the amplifier tube could conduct briefly without the cathode
>bias relay being closed. Naturally a current pulse would cause the anode
>circuit to ring at its vhf self resonance, and a vhf parasitic oscillation
>just might be possible.

I'm open-minded on this, but we seem to be talking about a sudden arc-over rather than a specifically vhf parasitic oscillation.

Jumping across to the other branch of this discussion that deals with gold sputtering, I don't see how anybody - not even Eimac - can say that sputtering effects "must have been" caused by vhf parasitic oscillation. That kind of hindsight does not exist. All we know for sure is that the sputtering was caused by heating, probably directly at the gold surface of the grid wires rather than from the inside out. Large vhf currents concentrated on the surface by the skin effect could be one cause of surface heating; but not the only possible cause - see later.

Another piece of evidence, that doesn't fit in with intermittent vhf parasitics being the cause of the sputtering problem in HF amps, is that the 8877 and 3CX800 can be used all the way up to 432MHz, at and above their rated maximum power. Yes, there have been a few tubes catastrophically destroyed, but what'ya gonna blame for that - shf parasitics?

The other main cause of surface heating in vacuum tubes is of course particle bombardment. We can accept the evidence that incorrect operating conditions will damage the grid due to over-dissipation (excessive grid current), and obviously the worse this abuse, the sooner the tube will fail. Maybe different mechanisms will be at work over different timescales (seconds - hours - months) but this is all quite different from the catastrophic mode of destruction where it's all over in a small fraction of a second. Those are two totally different modes of failure that really shouldn't be discussed together.

It seems reasonable to use electronic protection against damage caused by incorrect operating conditions (grid currents up to maybe 10x the rated value). But it's not reasonable to complain that the same circuit doesn't protect against catastrophic damage (grid currents which Rich estimates at say 15A).

So where does the catastrophic damage come from? If it's capable of doing so much damage to the grid, even when the cathode is back-biased in standby mode, it seems that the current must be sourced from the anode.

Gary points out that electrons striking the grid from the cathode have neither the mass nor the volts of accelerating potential to do much damage. On the other hand, positive ions sourced from the anode would have several thousand times the mass and an accelerating potential of several kV - and all their impact energy is initially deposited on the surface of the grid.

The original source of the ions could be de-gassing as I mentioned earlier, but once the arc is running it would be self-sustaining. When the neutral atoms at the anode dissociate, positive ions flow from anode to grid (or screen in the case of a tetrode) and electrons flow the opposite way.

Unless my notion of the physics of an arc is all wrong, the arc theory seems to explain the available evidence without any need for rf oscillations as well.

A final clue from Rich:
>I received a telephone call this morning from a fellow in Reno whose
>had a blown grid fuse resistor, but whose new tubes were undamaged.

New tubes? Isn't that suggestive of a little too much gas, resulting in a liability to arc until the tubes are fully de-gassed by a few hours of normal operation?

I'm not taking sides here - this has been a very high-quality discussion among people whose expertise I greatly respect, even though they disagree with one another! I'm just thinking aloud (or whatever the Internet equivalent is), feeling my way forward and trying to piece together a story that fits all the facts...

As long as the antenna closes first, and opens last, you will be ok.

The amount of delay is unimportant, I'd make it enough to always guarantee a correct sequence, perhaps a minimum stagger of 10-20% of the slowest relay's response time.

2542. Converting a rig to positive CW keying

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-04 00:00:00 UTC
From: Monty Wilson <nospam@see.signature.part>
Message-ID: <E0D8J0.3K6@twisto.eng.hou.compaq.com>
Source record: 101046

I bought a CMOS memory keyer that has only a "direct" output; ie., can only key a positive voltage to ground. I was unable to use it to key my TS830S, a negative-voltage keyed transceiver. I built a two-transistor interface circuit similar to the grid-block output of the MFJ Econo Keyer, and this weekend installed it into the rig. It uses only parts available from Radio Shack and performs very well. If you can find a point in your rig where you can steal +12v or +9v it's a very easy mod. In the '830S it sits neatly on the pins of the key jack, and the +9V is right next door on the anti-vox control.

If anyone is interested, I can send a BMP file with the circuit and all the information.

My Drake TR-4C is out on loan. When it comes back home, it definitely gets one of these little boards. Now if I could just find that QST mod that gets rid of the AM/SSB grid block problem....

>wear the bracelet. :-)

That attitude presupposes the conclusion. A survey could be useful if
it documents problems experienced before and after the suppressors
were added. If failures are significantly less after installation
of the suppressors, we have to conclude they are working, whatever
the mechanism. If failures are still happening at a statistically
similar rate after the suppressors are installed, then and only
then can we assume that the suppressors are faith healing quackery.

We can't determine if there is a statistically significant universe
for this problem unless a survey is done. I expect we'd need a
cumulative number of operating hours approaching 100,000 from a
survey before we'd begin to have any confidence in the correlation.
Science often has to depend on correlations when mechanisms are
poorly understood, or confounded by many other variables.

Correlation cannot prove causation, but no correlation at all
can flatly disprove a causitive linkage (and that's how the copper
bracelet theory was disproven). Thus this sort of survey is useful
for disproving a theory. If the correlation is strong, however, then
there is good reason to proceed down that path and try to determine
the exact causitive mechanisms involved (which may prove to be subtle).

>
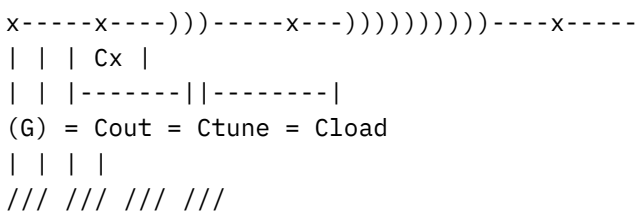
>According to aerodynamic theory, a bumblebee can not fly. However, >bumblebees in this neighborhood seem to manage a fairly good imitation.

Lets see if we can make some sense out of this. The output of a HF amp looks something like this:



Cout is tube output capacitance, Lx is the inductance of the plate lead, and Cx represents the intrawinding stray capacitance of Ltank. Ctune, Ltank, and Cload are the ordinary pi tank components resonant at the HF frequency. At HF, Lx and Cx are negligible and can be ignored (mostly anyway). Cout is effectively paralleled with Ctune.

At VHF, Cout and Lx form a L network. Or alternately, we can consider Cout, Lx, and Ctune as forming a pi tank with a very reactive load.

Note that the drawing assumes all the chassis ground points are actually common. In fact, there's a finite impedance between each one since they aren't at a single common point on the chassis. This can excite resonances in the output enclosure behaving as a cavity resonator. And if any of the component to chassis hardware is loose, very nasty things can happen because circuit topology is no longer what we think it is. We'll take a look at that later.

Ok, if we treat Cout and Lx as a L network, we find it is a step up network, so the voltage at the output end of Lx is high, but the network is shunted by a low reactance Ctune and is in series with a high reactance Ltank (if that reactance is very high, we can ignore it). Tom is saying that the very low reactance of Ctune (at VHF) is going to prevent high voltages appearing across it.

Now that's true, if Ctune has a reactance of lets say 1 ohm at VHF, it is going to take 1 amp of RF current through it to have 1 volt expressed across it. But we have thousands of driving volts to express across it thanks to the step up L network. Ohm's Law tells us the result is going to be a very high RF current flowing through Ctune. Of course the actual current will be limited by other circuit factors so we shouldn't expect air gap arcing across Ctune to occur at VHF.

Now, if we treat Cout, Lx, and Ctune as a pi tank resonant at VHF, the output impedance of the tank tapped across Ctune is still low, and Ltank presesnts a high impedance load, so while high currents may flow in Ctune, potentials shouldn't get high enough to cause air gap arcing.

Ctune's X may be low, but it may have considerable series R since it's a variable. If the series R is high, then the possibility of arcing exists if the series R is mainly on the chassis side of Ctune. In fact, it is usually the rotor which is connected to chassis, so the slip connection is on the low side. If spot heating occurs here due to the large circulating current, this resistance can increase (as well as the resistance of the mechanical connection to chassis). This can allow higher voltages to be expressed from the stator to chassis. Perhaps the voltage can become high enough to allow an arc. (This is somewhat unlikely, however.)

But now lets go back and think about the fact that the chassis connections are not really common at RF. For VHF, it is a finite portion of a wavelength back to the tube cathode, so we should expect to see some reactance there. That changes the network topology significantly.

The Amidon core can be had from Amidon directly. You should be able
to find their address in one of the ham magazines.

You can probably also get it from Dan's Small Parts. I don't have the
address handy, but he is on the WWW now, and you can find the site
by one of the search engines. He also has a selection of variable
capacitors. Probably you could find something suitable. Remember,
component substitution is the backbone of amateur radio. If you
can't find the exact capacitor, you can usually get away with something
else, if you understand things.

I don't know where to get prewound coils. The problem with a lot of
old articles is that they specify a manufacturer's part number, rather
than hard data like inductance etc. This means you'll have to find
out what the parts numbers mean before you can substitute. A tv
set will turn up plenty of small diameter coil forms, though the tuning
slugs are intended for a certain frequency range. Winding coils is
easy, once you have the basic data. The ARRL handbook should help
with the background.

Hope this helps for a start.

>
>.... and all that wide open space on 6m and 220 MHz ??...

Excuse me, 'wide open space' on 222 MHz? Then why did the last 220 SMA meeting feature a hearing due to a denial of freq. coordination to a repeater on Blue Ridge, and why were there 2 freq. coordinators on 222 MHz in So. Cal. for a while? The 222 MHz band may not be used as much as 2 meters, but it's stuffed full of repeaters. There is some room on 6m, but it's awfully noisy.

I'm not sure we can blame Mike for the mess on 446.65. He is only a pawn of SCRRBA, which apparently decided that the frequency shall not have an 'open' repeater on it. The 'warning' transmitter cites references to SCRRBA coordination, but makes no mention of possible coordination of KJ6TQ by other freq. coordination entities, so it is not accurate to say that any other repeater on the freq. is uncoordinated.

>simultaneously?

There sure is. The output relay should close first. You don't want
to apply drive to the amplifier before there is a load on it. One
way to insure this is to use a relay sequencer. Another is to just
use a faster relay for the output than the input. Vacuum relays
are usually faster than ordinary open frame relays, and are often
used for amplifier output switching.

> meric@feynman.arc.nasa.gov

Meric,

I agree with you, however some points NEED clarification.
If in your case you specified that the collector voltage was
held FIXED at Vcc/2, INDEPENDANT of Rc, then your
statements of gain being independant of Rc would be true.
But if this were the case you would have effectively
turned your collector resistor into a CURRENT SOURCE.
By that I mean changing the resistor value incrementally
has the effect of changing the collector current incrementally,
ie changing the operating point. Your original statement
did not include any of the important biasing details.

If the transistor is biased by forcing a particular BASE/EMITTER VOLTAGE, ie the collector current is relatively independant of Rc, then you have simply identified a case where your equations are correct. But the claim that gain is independant of Rc is NOT correct, and is misleading. As proof of concept I suggest that you now incrementally change the Rc value to Rc+r. No longer is the collector voltage equal to Vcc/2, and guess what, the magnitude of the gain is now gm*(Rc+r)! (yes I am ignoring Va effects here for simplification). By this I mean that the operating point is determined by a forced base/emitter voltage, perhaps by a simple voltage divider.

So as I would summarize, If the transistor is biased from a current source and the collector voltage is set by some sort of feedback mechanism, the gain (which is ALWAYS gm*R), of that stage is pretty constant ONLY if the Ic (gm) is inversely related to a change in R. gain=gmR gain=gmR gain=gmR.

I apologize in advance if I have overstated the obvious, however when I read your analysis of gain independant of Rc, I felt that some additional details should have been more explicitly stated to support your claims.

Hi Wes,

If you read back through this mess you'll see I pointed that out early on. I just made the comment in passing, but it is an important effect.

Eimac does factor that into the grid dissipation rating they give, so there is no need for the designer to consider it. The assume in the real world of PA's that the operator has the heater on.

Of course, I wouldn't be amazed if someone said THAT wasn't true. ;-)'

>theory. It originated at Eimac. I am only the messenger.

Hi Rich,

Eimac claims you are mistaken, and have distorted a letter written by someone assigned to answer customer service letters. Anyone with a first year physics book can see how unplausable that theory is, and Eimac even states the damage is excessive grid current caused, and the only case of that they had was in very large transmitting tubes for UHF, and the oscillation was microwave heating of the grid.

If we can move beyond that, I'd like to hear why you think a resistor makes a good fuse for a control grid. No big stories are necessary, just the facts about failure time (until the resistor opens) vs amount of overload.

I need help understanding that postulation. I've always understood electronic overloads are much faster than fuses (which are notoriously unreliable), and I've never seen anyone suggest using conventional resistors as fuses for delicate devices.

Unless you'd rather clarify the arcing tuning capacitor. That's another area that makes no sense.

Yes, the output relay MUST close first and release last, or you can ruin the bandswitch or other components (including the output relay).

Who are the most important manufacturers of PIN diodes ?

Can you give me examples for a TR switch in the 100 W range at 150 MHz ?

Can a slow rectifier be a low cost replacement for a PIN diode ?

Many thanks.

I tried Measure's lower Q suppressors. It didn't help my
SB-220's intermittant "arcing". I changed the
grid circuit to 6 wide ground straps, and that
seemed to help.

A couple of weeks ago the amp started arcing
at power on, every time. I finally traced it this
weekend to an undersized .001 bypass cap
in the hv supply circuit. Little pieces of the
1/4 in diameter cap were blown off the back.
(This cap looked too small to be original equip.)

Was that my problem all along? Only time
will tell.

>that a steady 6W is going to raise the temperature of the grid structure
>to over 2000 degrees F?

My posts take a while to appear, the system I use is slow.

You don't seem to understand how to calculate grid dissipation Rich,
please read this carefully.

Grid dissipation is given simply (as is the anode dissipation at any given
instant of time using Epk*Ipk) by the grid to cathode voltage while the
grid is conducting.

When the output circuit is proper loaded in a gg amp, negative feedback
occurs. This feedback lowers the g/k voltage. In this condition, the
effective RMS grid voltage is lower.

If the PA is anode is underloaded (too high a load impedance presented),
negative feedback is removed and the g/k voltage and current soars. This
happens rapidly with small changes in load impedance with tubes like the
3CX800, and slower in low mu triodes. That's one reason why low mu triodes
are prefered in PA's with unstable loads.

So your voltage assumption, like so many others, does not hold true in
practice. It not only isn't the correct g/k voltage in the untuned
condition, it is wrong in a properly loaded PA.

The effective g/k RMS voltage of a single 3CX800 in a PA I actually
measured (as part of a routine design proceedure) was over 100 volts when
the stage was mistuned enough to allow 150 mA of grid current to flow at
full exciter power.

You seem to be ignoring several circuit parameters, like conduction angle
of the g/k path. It is less than 180 degrees, so the voltage is higher
that it seems at first glance because the peak current is also much higher
than the meter indicates.

Please read the copy of correspondence from Eimac that I posted, they also
claim (as I do) that the damage is commonly and most likely from improper
load or loading of the PA.

2574. Filters

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-04 00:00:00 UTC
From: d.NOrdquest@juno.COM
Message-ID: <19961104.122329.4783.0.d.nordquest@juno.com>
Source record: 101135

Hi Gang,
Wonder if you could clarify a point or two about filters. I'm modelling a filter for a DDS which should let frequencies up to 16Mhz through and stop those above 24Mhz.
Using FDS.EXE, I've synthesized innumerable filters, which I've then modelled in PSpice. The specs don't seem to coincide exactly with the modelling. Anyway, I'm going to need a 7-pole elliptical filter with about 60dB of attenuation. The passband voltage with my present model changes from about 1.1 to 1.7 volts. In the stopband it goes down to about 1.2mV or lower, according to PSpice. Figuring power delivered to a 50 ohm load, that's 50-some dB of attenuation, I assume.

My first question is whether this theoretical performance sounds reasonable?
The second is what zeroes are in filter modelling and, particularly, what order the elements corresponding to the zeroes should be placed in a filter. FDS lists the zeroes in the order 1,3,2. I assume they are the series-parallel capacitor/inductor elements across the top of the filter and that they are numbered 1,3,2 from left to right.
Am I right?

Thanks!
Dave KE9ED

Hi Tom,

In article <55kjg9$7ki@camel2.mindspring.com>, tomwagner@mindspring.com (Tom Wagner) writes:

>I tried Measure's lower Q suppressors. It didn't help my
>SB-220's intermittant "arcing". I changed the
>grid circuit to 6 wide ground straps, and that
>*seemed* to help.

The SB-220's largest single design defect is the grid chokes and small caps from the grid to ground. The parallel L/C combinations causes a parallel resonant circuit form the grid to chassis, while the ESR and inductive reactance of the leads of the bypass caps LOWER the self-neutralizing frequency of the 3-500Z's.

All of this is bad news.

The SB-220 can oscillate at VLF, not VHF, because of this IF the load impedance is correct. That involves a load that resonates the plate choke, via the blocking cap, at VLF. Removing the chokes and grounding the grid improves several parameters of the PA.

In article <FUwccBAOkNfyEwY7@ifwtech.demon.co.uk>, "Ian White, G3SEK" <G3SEK@ifwtech.demon.co.uk> writes:

>Such conditions do not exist in a normal vacuum tube. If there is a

>more likely to be due to a release of a micro-pocket of trapped gas, or
>a flake of material falling off one of the electrodes. It doesn't seem
>to be necessary to invoke cosmic rays to explain this.

That is absolutely true Ian, while I don't know much about quantum or nuclear physics I do understand tubes and their behavior, having designed PA's commercially for over 20 years.

Nearly everything offered to support parasitics flys in the face of science.

Let me give a clear example.

Rich theorizes the parasitic causes large anode currents, yet very special conditions are necessary to do this.

1.) The tube is simple a variable resistance load that "tugs" the rest of the circuit and gets it going. If the impedance of the resonant load is low, the current will be high and voltage low. If the impedanbce of the resonat load is high, the voltage will be high and the current low.

Maximum power is converted (the PA is a dc to RF converter) from dc to RF when the tubes dynamic operating impedance conjugately matches the load impedance.

2.) The cathode current of a tube is limited at a specific saturation current. If we tried to intentionally draw the amount of current Rich claims happen via an emission process, we couldn't do it. Not even with thousands of volts of positive grid bias!

You gas theory agrees with the facts surrounding the failures, Eimac supports that, it has been my experience that gas is the number one thing causing catastropic arcs.

If a resistor is placed in series with the grid, it reduces the intensity of these discharges by increasing path resistance. But that is the wrong location. A resistor in the grid to chassis path allows the grid to go very positive in respect to the cathode during an arc, and a large pulse to pass along to the cathode as a secondary arc path.

The correct approach is to ground the grid, and insert the resistor in the dc anode supply line. In that case the energy of the arc to the grid is reduced, and the grid is grounded preventing the grid cathode voltage from soaring.

This is a case where one of Measure's suggestions can help one problem but create another.

>Jumping across to the other branch of this discussion that deals with
>gold sputtering, I don't see how anybody - not even Eimac - can say that
>sputtering effects "must have been" caused by vhf parasitic oscillation.
>That kind of hindsight does not exist.

That's correct Ian. All we know is it was overheated. We don't know if it was from dc or microwave energy.

>Another piece of evidence, that doesn't fit in with intermittent vhf
>parasitics being the cause of the sputtering problem in HF amps, is that

Try Mouser Electronics. If you are going to put one in the anode, voltage rating is important. You will be much better off with a little less inductance for the anode choke, and higher breakdown voltage.

>
>I think we have to assume, given what we know about real components,
>that the tuning capacitor has long since gone series resonant and
>probably appears, at VHF as a rather high value of inductive
>reactance.

Not at all Fred.

There are two self-resonant points of the Oren Elliot 250 pF capacitor used in the AL80B withing the range of my 1-1000 MHz Impedance analyzer.

With the cap open, the series resonant point is 489.1 Mhz where it looks like .23 ohms j0 and another where at 570.74 MHz where it measures 14.1 ohms j 0.

These points move to 170.4 and 289.9 MHz when the cap is meshed. I can find no anti resonant impedance in the range of 1 to 1000 MHz.

You'd be in radio hell trying to drive that cap with RF at VHF or UHF and make it arc.

>I don't believe we can assume that the anode circuit
>provides much loading for VHF.

We don't need to assume anything. We can measure it. And it is very low (<300 ohms scalar) over the range of 50 to 1 GHz in the 80B.

>And if the VHF frequencies are, by and
>large, unloaded, it doesn't take much gain to make the circuit
>unstable. We're dependent, I think, on keeping VHF out of the grid to
>cathode circuit to keep circuit stability.

The plate impednce is low, except in crummy tubes like 811A's, 572B's, 450TH's, 833A's, and so on. They have long thin anode leads. They also have long thin crummy grid connections. If you look at amplifiers designed with those tubes, you will see large parasitic inductances are required along with higher values of resistance. That's because the loading resistance has to across an appreciable portion of the inductive path from anode to RF bypass (the tuning cap). Since the lead inside the tube is so long, the inductance outside the tube the resistor is across needs to be larger.

Since the grid lead is so long, the frequency of oscillation is lower. That forces us to apply damping at a lower frequency. Looks at the size of the inductor in an 811 amp compared to a 3-500Z (not the Heathkit 220,

they screw up the grids with the series caps). There is typically a 5:1 ratio between them in suppressor inductance.

>That's not what the tube engineer who disassembled and inspected the two,
>8875, s/n G8AD-241 and s/n F8VD-4283, tubes told Mr. Foote, according to
>Mr. Foote.

Let me see if I follow this. Someone else opened the tubes and told Foote
the damage was caused something other than excessive current. Next Foote
told you what that person told him verbally, and now you are telling us.

I wonder who the source engineer was and what were his exact words were.
Do you have a letter from him?

>> and Bill Foote, then responsible for writing letters related to

>> Measures.

>My conversation with Willis B. Foote in Feb. 1986 had nothing to do with
>microwave oscillation in a high power UHF-TV amplifier klystron.

It wasn't a klystron Rich. Did I ever say it was? It was a power grid
triode.

>I have not stated that parasitic oscillation is the only means of
removing
>gold from the grid.

You have stated:

1.) That a tube grid can not be damaged from fundamental frequency
excitation.

2.) That electronic protection should be removed

3.) That resistors make good fuses, and fuses are alos good for protecting
grids.

4.) That skin effect causes gold to leave before the base metal

5.) That gold only leaves when it boils

All of which are untrue.

>However, when gold sputtering takes place at the same
>time that tune capacitor arcing takes place, in an amplifier that was
tuned
>up correctly, an atypical event probably took place.

Now let's see if I follow this, if the capaciator arcs at the same time
the tube fails, it is an atypical event taking place. Perhaps. But let's
examine that.

We know that it is virtually impossible for the capacitor to be driven by
enough VHF or UHF current to flash over, that's easy to prove. We know the
grid can be damaged by any frequency from dc to light that causes
excessive heating, and the heating is electron bombardment on the grid and
not I^2 R losses in the grid.

What happens in an unprotected PA?

If the PA is underloaded and excitaion remains at a high level, several
things go on. The tube continues to "tug" the tank circuit in
syncronization with the resonant frequency. The tank can swing freely
negative (below zero or the chassis reference) since nothing loads it in
that direction. The longer the time the anode of the tube spends negative,
the shorter the conduction angle of the anode is.

When the tank goes positive, the tube is also well on its' way to cutoff.
The tube is cut off very hard because the light anode loading removed most
of the negative feedback. The tank is free to overshoot in the positive
direction because the tube is cut off and there is little load on the
tank.

Tank voltage soars, limited only by losses in the system at the
fundamental frequency. The peak to peak voltage swing can be several times
the dc anode supply voltage.

A diode across the coil will slow the release time. A cap across the coil
with a series r will slow the attack time.

I use a parallel cap acoss the coil and a series diode/resistor on the
input relay, along with a diode across the output relay in one case.

I am conducting this survey to gather data on buying and consumption patterns of Americans. It should take about five minutes to complete. The data will be used in a research paper I am writing for an English class, the purpose of which is to organize data from a number of different sources into a coherent whole. Please respond by 7:00 p.m. on Wednesday, November 6th, 1996. When appropriate, check one or more options that apply. Thank you for your time.

1. Age:

2. Gender:

3. Where do you live? (city,state)

4. Education Level: Highschool or lower_____
College or university_____
Graduate school or higher_____

5. Occupation: Student_____
Other(please specify)_____

6. Marital Status: Married___
Single___
Divorced___

7. Household Income: One main income___
Two incomes_____
Other (loans, PT job, parents, investments, etc.-please specify)_____
8. Do you drink alcoholic beverages? Yes___ No____ (If "No", go to number 20)

9. About how often do you drink? 1 to 2 days a month____
1 to 2 days a week_____
More than twice a week_____
Almost every day_____

10. About how much do you spend on alcohol per week?
$0-$5_____
5-10_____
10-20_____
more than $20_____

11. Do you usually drink at: Home_____ Bars_____ Parties_____

12. Do you believe that the amount of money you spend on alcohol is:
About average_____
Above average_____

Below average_____

13. Is your usual drink a: Domestic beer(Miller, Budweiser,etc.)_____
Imported beer_____
Microbrewed beer_____
Mixed drink_____

14. About how long have you been drinking?
under 5 years_____
5 -10 years_____
10-20 years_____
over 20 years_____

15. When you go to a bar, what usually determines where you go?
Drink Specials_____

Bob: If you have the Bird model 4430 with interal sample port coming out
the side. The specs from Bird catalog are "RF coupling -53db from 512MHz
to 10Mhz, decreasing to -70db between 10MHz and 2MHZ". If you have the
sampler that bolts in series with the coupler model 4275 (20-1000MHz) or
model 4273 (1.5-30MHz) the coupling is adjustable from -35db to -70db,
with quite a bit of roll off(less coupling) as you go lower in frequency.

Hi Jesse,

First of all, I never said the nichrome was harmful. It is a less than desirable way to do the job, but anything that gets the job done is OK by me.

The things I object to (concerning parasitics) is this:

Everything gets blamed on them. Tank caps arcing, tube failures, bandswitch failures, relays arcing WHILE THE AMP IS ON STANDBY, meter failures, diode failures, and so on. That's pure bunk, and we are threading our way through that.

Every failure has a cause, and they are generally easy to determine. It would be nice to have one thing that causes all the problems in the world, we all love simple one cause explainations.

In article <327f63ff.1482030@news.frazmtn.com>, w6kkt@frazmtn.com (W6KKT Jesse) writes:
>I installed the low Q suppressors as precautionary measure, in two
>Henry, one Heathkit SB220, and a 4-1000 amp. The change that I
>noticed was the amplifiers seemed to tune "smoother", elimination of
>the random rf "popping", and had about a 0.5db loss of power on 10
>meters.

Esoteric testimony always includes works like "seemed". Another person posted he used nichrome in his 220, and still had problems. Perhaps we should destroy all the textbooks, and go by public poll? Then we won't learn anything.

The 220 has one major design defect. The grid chokes (I already posted this) WERE an engineering mistake. Look back and you'll find it. That mistake is an interesting topic all on its' own.

>Will I take them out because of the recent negative
>threads as to their use posted in this group and written in QST?

That's a disappointing comment. Everyone has a chance to look at the facts here. Just because a few outlandish claims are being taken apart technically this should be viewed as negative.

All the data I've given can be verified. This is science, and simple theory. We are just getting into the real reason WHY an amplifier arcs. Once that's all covered, IF we can stay on track, you can decide what to do because you'll know exactly why failures happen. None of it is strange, and all of it has very good easy to understand reasons.

Personally, I think we are covering things pretty well. If something doesn't make sense pipe up. I can't argue feelings or personal opinion, but with over $100k of RF test equipment and dozens of PA's here I sure can measure things. If you have a $169 MFJ 259 you can measure the same things with less accuracy.

Let's stay with theory, measurements, and documents. Otherwise we'll never get to the real problems.

Check some audio speaker catalogs for a tweeter manufactured by
Motorola. These small black plastic horns contain a piezo element and
are good for a few watts. put a few in parallel to dissipate the power.

If there is enough intrest, I will post a small article in this news group regarding how to build a UHF/VHF amp from pre-existing mobile radios that could yeild 25-150watts with only 500mw-2watts drive (depending on amp module). All that would be needed to make units fully functional for amateur use is a T/R Switch. I have built several of these units for my repeater and have tested them on a spectrum analyzer and have come out looking great. The only rule applies is a bad signal in will give you a very strong bad signal out. The cleaner the signal going in will give you best results...If there is intrest please reply with e-mail and I will come up with a posting...

thanks 73 de n9osk - Shawn S-O-S Electronics Corporation.

> Is that the only difference?

Hi Alex,

Bipolar PROMs are generally TTL or ECL. They are programmed by
fusing Ni-Cr links organized generally in a matrix (or mask
programmable at factory if you buy by 10,000 :) They are very
fast in the 5 to 50 ns range generally.

EPROMs and EEPROMs are most of the time CMOS and programmed by
charging/discharging small "capacitors" inside. They are erased
by exposition to UV (EPROM) EEPROM are Electrically erasable...
If you make a mistake you erase and redo.

Programming is different in Voltage and timing. Small Bipolars
can be programmed by hand (switch bank for address, for data and
push button to ...program) if you know how much Voltage and current
is needed to fuse the link. If you make a mistake the PROM is finished!

I have seen some PC cards which could program common EPROMs but
it is expensive for a one shot operation. Some dealers do the
programming for a small fee (10$) if you can bring the binary
file to do it (generally Intel Hex format).

If you go to my page, there are some Electronic Links to most
manufacturers and other info on components etc. You may even
find the spec sheet for your PROM/EPROMs

Good luck with your project :)

I use a pair of DowKey relays on my 2M amplifier (~300 watts)with no controlled sequencing within the pair (i.e. their colis are in parallel). However, the pair is sequenced relative to the receive preamp and driver PTT so that RF drive is not applied until both relays have had time to close.As long as the time is longer than the slower relay it doesn't really matter whether the input or output relay closes first. BTW I am using the ARR commercial sequencer board, modified with an interlock that prevents transmitting unless the preamp is out of the line.

Source record: 101061
Cross-posted to: rec.radio.amateur.misc,rec.radio.amateur.homebrew,sci.electronics.design,sci.electronics.components

There are many, Hewlett Packard 5082-3201, 5082-3202
5082-3203, 5082-3204 are all rated for 120watts when
used as a series 50ohm switch. They are useable from
T10Mhz to 8 Ghz and can be purchased from Penstock at
408-745-8100. The ARRL UHF/Microwave Project Manual
has a lot of info on PIN diode switches.

PIN diodes are special in the fact that they are
a diode with a intrinsic layer at the junction (PIN =
P Material + Intrinsic Layer + N Material). They
are very close to being equal to a pure resistor at
RF frequencies (low L & C) and exhibit very low
resistances (<1 ohm) when forward biased but very
high resistance when reverse biased (> 10K ohm).

To learn more about PIN Diodes contact HP and
request (or you might have to buy) their GaAs &
Silicon Products Designer' Catalog.

Hope this helped!

>topology significantly.

I think we have to assume, given what we know about real components, that the tuning capacitor has long since gone series resonant and probably appears, at VHF as a rather high value of inductive reactance. I don't believe we can assume that the anode circuit provides much loading for VHF. And if the VHF frequencies are, by and large, unloaded, it doesn't take much gain to make the circuit unstable. We're dependent, I think, on keeping VHF out of the grid to cathode circuit to keep circuit stability.

Hi everybody!

I have a problem again.What is the difference between an E-PROM and a

BI-POLAR PROM ? Can you program a BI-POLAR PROM on an E-PROM programer,

as far as I know E-PROM is erasable and the BI-POLAR PROM is not.

Is that the only difference?

Please help

Hi Rich,

In article <measures-04119607421900001@port26.vcnet.com>,
measures@mail.vcnet.com (R. L. Measures) writes:

>Who at Eimac currently claims that I was mistaken and that I have engaged
>in distorting a letter?

Actually it isn't just one person, it's the entire staff. A better
question might be can you give the name of one person in Varian
engineering supporting your claims?

>Is this person perhaps one of the 6 participants
>in the 5500-word critique of yours truly in the Sept., 1994 *QST*---the
>critique for which I was not allowed the courtesy of a rebuttal?

Since your very first article, Varian (Eimac) and perhaps a dozen other
individual people have asked and communicated to QST that the claims made
were incorrect.
If QST is guilty of anything, they are guilty of not sending your material
out for technical review, or allowing others to challenge your claims. You
had page after page of featured article space to spread technical nonsense
around, until now whenever a simple problem comes up it's blamed on a
parasitic.

You lay blame on "6 participants", yet those six were selected from a
large stack of letters. Even at that, your articles were sent out to a
large number of brand new non-participants and they supported the letters
of disagreement.

Please don't think for one minute six people "just don't like you". You're
a talanted writer, and a likeable guy with good word command. It's just
that many of the theories you developed are not accurate. It's technical
disagreement, nothing more...nothing less. Anyone makes these kinds of
mistakes when they work alone, that's always a problem without outside
collaboration or review.

I think magazines should check articles out and help authors and readers
before things get published, not after the fact. But what's done is done.
I'd rather have seen a moderated discussion of the issue, but it wasn't in
the cards. Finger pointing does nothing constructive, QST made a mistake
(by not checking out stuff before publication), and that's that.

> The person at Eimac who wrote the letter I allegedly distorted was
Willis
>B. Foote, Eimac's Chief Specifications Engineer in the Power Grid
>Division. The letter in question can be read at:

>http://www.vcnet.com/measures/EimacF.html

Rich, I miss something when I read the letter. Here's what I understand:

1.) It says YOUR letter about your theory on parasitics was interesting.

2.) It said the tubes were badly overheated inside. "Apparently the result of an oscillation".

3.) It says if the grid is overheated, gold vaporizes off and ruins the tube.

The only time it mentions parasitics is when it thanks YOU for the interesting letter about parasitics.

I don't understand how it says "Parasitics damage grids of tubes, but fundamental RF excitation does not." Can tell me what I missed?

>BTW, Tom, I am still waiting for an answer to the question I asked on 3 Nov.:
>> >Tom: What is the rated grid-dissipation for the 3CX800A7?

4 watts.

My Sony ICF-SW 7600 radio (Italian version) covers the following frequency range 150-285 KHz step 3 KHz, 531-1602 KHz step 9-10 KHz selectable, 3850-26100 KHz step 5 KHz, 88-108 MHz FM step 50 KHz.

The American version of the same radio covers the LF,MF and HF frequencies with the range 150-29995 KHz. I would liKE to obtain the same HF frequency range as that available on the American version but the frequencies 1602 - 3850 KHz and 26100 - 29995 KHz are not receivable on the Italian version!

The radio is controlled by CPU, it has a PLL utility, is equipped with a keyboard and can store 10 items in memory. The receiever is 48055 and 455 KHz double version and demodulates AM and SSB.

At power on the CPU checks the jumper configuration (LW, step 9-10 KHz in MW, SW, FM). Setting the LW jumper to OFF extends the frequency range from 285 to 531 KHz, while setting the FM jumper to OFF extends the FM range from 76 to 88 MHz step 100 KHz. Setting the SW jumper to ON or OFF has no effect, the frequency range remains 3850-26100 KHz in both cases.

* Does anybody have the ICF-SW 7600 schematics?

* Does anybody know how to extend the frequency range from 1602 to 3850 KHz and 26100 to 29995 KHz?

Please send your reply to my e-mail address, as detailed below.

Thanks.

Chalp Maurizio Olivetti (Italy)

That's not what the tube engineer who disassembled and inspected the two,
8875, s/n G8AD-241 and s/n F8VD-4283, tubes told Mr. Foote, according to
Mr. Foote.

> and Bill Foote, then responsible for writing letters related to

> you make your life more enjoyable, do something else than arguing with
> Measures.
>
Hmmmmmm. An UNSIGNED letter, offered as evidence. Very curious, me
thinks. Who wrote the unsigned letter, Tom?

My conversation with Willis B. Foote in Feb. 1986 had nothing to do with
microwave oscillation in a high power UHF-TV amplifier klystron. Foote did
not work in the klystron div. He was the chief specifications engineer in
power grid. The 8877 is a power grid amplifier tube. The 8877 is not a
klystron tube.

I have not stated that parasitic oscillation is the only means of removing
gold from the grid. However, when gold sputtering takes place at the same
time that tune capacitor arcing takes place, in an amplifier that was tuned
up correctly, an atypical event probably took place.

Tom---Have you answered the question I asked you about the inductance of
the Matsushita film resistors we use in our parasitic suppressor retrofit

kits? Have you answered my question about the rated grid-dissipation for the 3CX800A7?

Interesting analysis, Gary. There are so many variables at VHF, it's mind boggling.
I remain convinced that the energy involved is probably well above HF. The simultaneous occurance of an extreme grid current pulse indicates that the amplifier tube is virtually unloaded during the event. Therefore, the amplifier tube is most likely producing substantive amounts of energy that can not pass through the (low pass) HF tank circuit. Another factor is the colour of the arc. I have seen HF arcs before. This is different. However, analysis is compounded by the intermittency factor.

Part of the answer may be that we are assuming that the tune C has no series-L and only an 1 ohm or so of reactance at VHF. However, in a 922, the tune capacitor has roughly 20 ohms of reactance at the frequency of the apparent VHF oscillation. In a SB-220, the tune C has roughly 25 ohms of reactance at the frequency of the apparent VHF oscillation. RE: series-L in the tune-C: Many people assume that wide, flat conductors have zero inductance. However, this is not true. Even superconductors have inductance.

In a previous post, I broached the subject of the possiblity of developing high potentials from a 120v 60Hz source, using only one capacitor in series with one inductor.

Does anybody remember the WW2 radar transmission-lines that used copper
'insulators'?

> Dan.Dan:
The majority of wx radars work at 5 Ghz, so your first task will be to
assemble the necessary RF parts:
1. Antenna - prime focus parabolic reflector antenna with dual
polarization feed and an orthomode transduce
2. Tx - a simple magnetron with suffice for your activities. This will
provide you with a rough pulse transmitter - the spectrum wont be pretty
but it will work
3. Rx - you will probably get by with a single mixer diode front end with
a Gunn LO, the IF output frequency will depend in large measure on how
fast your DSP board runs

A word of advice: this is a big project. If there is a C band weather
radar at your local airport or met station, you may want to make a visit
and start asking lots of questions

Sounds like an old crystal-plexed rig. I've never converted that particular model, but in general the crystal-plex conversions are simpler and have better odds of success, but are more expensive because you must replace four or six crystals versus the one or two for the PLL rigs. One good resource is the CB-series Sams Photofact, available at your library. Look up the model in the Photofact index, also at the library, and you'll find the Photofact CB-series issue number that contains all the drawings and schematics for your radio. There are old "73" and QST articles from the 1977-1980 time frame that help with these conversions, but I don't have the issue dates handy. Anyone have these?

For a top-notch SSB rig, there are just a few things to be done. The first (at least I do it first) is the frequency conversion itself. The other various conversion things to be done to a radio vary depending on the particular type of rig, the original operating mode (AM or AM/SSB), the desired 10m or 12m operating mode (AM, FM, SSB, CW, combinations), and other desired features, but first we must see if the rig will go to the new frequency.

Once the new crystals are in place, with a voltmeter, oscope (need not be a calibrated scope; a Heath cheapie will do), a scanner (to verify frequencies by listening to harmonics of the desired oscillator frequencies) and a package of those plastic tuning tools, go through the transmitter strip and the receiver strip, as described in the magazine articles, bring the radio up or down in frequency.

Now for an SSB rig you want to do two things that I know of. The clarifier must be "opened" so it slides +/- 6 kHz instead of the stock +/- 1 kHz, and it also must be made to vary the transmit frequency as well as the receive frequency. This may still leave "holes" in the frequency coverage, depending on the crystal plan you've selected, but it will bring you very close to 100% coverage of the desired band.

The "opening" of the clarifier is accomplished by changing values of capacitance, and possibly adding a small amount of inductance, in the clarifier circuit. The change from RIT to RIT/XIT is accomplished by

disabling whatever method the rig used to prevent the clarifier from
swinging the oscillator when in transmit mode. The most difficult are
the ones where the clarifier swings an oscillator that doesn't even run
in transmit mode, but I think those are the exception rather than the rule.

Good luck, and have fun on the upcoming cycle.

>
>
> Fred

I agree, Fred. The VHF loading is probably light.
VHF-loading in the anode circuit should be a function of the R in the series of anode circuit conductors between the anode and the tune-C. In order to visualize this, it is helpful to measure the L of each conductor and then to convert the series-L-R-circuit to an equivalent parallel circuit between the anode and chassis-ground. . This way it's easier to see that as series-R increases, parallel-R decreases. Since the voltage gain of a triode is basically mu multiplied by the parallel-R, the bottom-line is that increasing series-R in the path of the VHF-resonant anode circuit, lowers the VHF gain of the amplifier tube. Does increasing series-R sound like it would decrease or increase the ability of the amplifier tube to oscillate at VHF?

Hi Tom, at the moment I'm not wearing copper bracelets (perhaps in
the future?). After reading the articles in QST (by Richard Measures)
I installed the low Q suppressors as precautionary measure, in two
Henry, one Heathkit SB220, and a 4-1000 amp. The change that I
noticed was the amplifiers seemed to tune "smoother", elimination of
the random rf "popping", and had about a 0.5db loss of power on 10
meters. I have talked with many, many hams on the air who have also
installed the low Q suppressors (i'm surprised I'm the only one on
this group who will admit using them), As of this date, I have not
heard or talked with anyone who has used, or is using these suppresors
that has had a negative experience due to their installation, myself
included. So, have they helped? I don't know! I havn't had any
related problems with the various amplifiers that use these
suppressors. Will I take them out because of the recent negative
threads as to their use posted in this group and written in QST? No.
Will I throw away my wonderful book Reflections (by Walter Maxwell)
because QST and a FEW of its board members disagree with some ot it's
content? NO! Will you pay for the repair of my linear should it

2621. FS/trade: Lab-grade test equipment for your next project

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-05 00:00:00 UTC
From: af104@detroit.freenet.org
Message-ID: <55nj85$oa0@lex.zippo.com>
Source record: 101082

Please forgive the intrusion of this "FS/Trade" post, but hopefully
it might be of value to someone looking for test equipment for his
homebrewing.

I would consider any amateur gear trades.

The following lab-grade test equipment is manufactured by
LEADER Corporation:

*** Leader LS1020 20 mhz scope

For details, see page 12 of Tuckers latest Test
and Measurement Equipment Catalog. They sell it new for
$525. Buy mine used for $175. 20 mhz, 2 channels, very
light.

*** Leader 27A Audio Generator

Covers 10 HZ through 1 Mhz. Sine / Square wave outputs. $45

*** Leader LSG-16 RF Signal Generator

100 khz - 300 mhz. 1 khz internal modulator. Also accepts/tests
your crystal for crystal controlled output. $65

Also have Elenco-Precision 0-30 Volt, .5 Amp adjustable power
supply. Separate voltage and current meters continuously monitor
output. Current limiter with overload indicator. $20

No books. Good condition, but some corporate ID info painted on.
Prices include freight to lower 48 (slightly more west coast /
mountains).

>another matter.

I use two multi-pole relays, one of normal 'fast' speed and another one RC-slugged to give slow make, slow break. Various make/break contacts on the two relays are interlinked to give the switching delays. 100ms sounds about right - long enough so that the two relays go noticeably "ker-lick".

The most important thing is that the coax relay contacts have plenty of time to switch over AND FINISH BOUNCING before you hit them with high-power RF. Allow extra time in case a relay might stick occasionally before starting to move. On returning from TX to RX, allow time for the RF power to disappear before moving the coax relays.

This system works by leaving enough time for the necessary things to happen, so isn't as reliable as a system that's fully interlocked. OTOH (FWIW, YMMV etc) after 10 years I'm still running a full kW at 432MHz through the same "500W" coax relay, and it has never blown a GasFET in the preamp.

Message-ID: <01a8edc0$4d409520$52672399@tricia>
Source record: 101085

At one time in my schedule, amplifier design for the hearing impaired was very interesting, some of the concerns included topics generally talked about now in the news group. I would like to jump in and suggest a high gain amplifier. Vowels you know au dominate the lower frequency spectrum <1000 Hz . The consonants that we most need are the upper frequencies 3000 Hz or >. For those persons hearing impaired be aware of those so called tunable telephones which give you gain, etc. Some do not. One is the XL-30 telephone. deficient by anywhere from 5 to 10 dB gain as advertised. These devices have the electret type, and some very clever earphone designs with very flat coil diaphragms. If anyone has a characterization type document I would like to know and help make it more public. I am currently building a site to include diagrams and such info. The amplifier design I am working on uses a biased internal line Operational amplifier BA3516. Has anyone seen this? its a quad split voltage I think. I will have the schematic on my site soon. If anyone is interested to pursue this jump right in. As I was looking at the questions here, the one about how much will a transistor amplify. If you have some documentation on the semiconductor, set up a small circuit and characterize the input load and the output load DC, and AC signal. Use a resistor and spread the values yes even for relating to an inductive load.

I found a schematic using a NE568 as an AM detector. It is in National
Semiconductor's data book. I have an older version, but I would imagine
it is in the new version too.

It is too complex to be entering into my computer, so I'm not doing that.

If you can't locate it anywhere else, send me an e-letter and I'll fax it
to you.

N O N L I N E A R

I'll skip the other ...

Seriously, Steve, whats' the problem ... many commercial radios have
been
built using this technique, and, believe me, the distortion will occur
much earlier in the simple deviation limiting circuits employed before
the NBFM modulator (been there, done that ...).

Jim

Geez, this is tough.

I did wind profiling radars for my research in Grad School, and it wasn't
the kind of thing I'd try for a simple thesis. Doing original research
might qualify for a PhD. thesis.

I would recommend keeping the frequency as low as possible. You can get
a good wind echo at 50 MHz (big antenna) or 900 MHz (more reasonable antenna).
You need an awful lot of power (10 KW peak pulse at 50MHz, if I remember
right). At 900 MHz you can get an echo off the wind, or off rain drops.
Really sophisticated processing allows you to distinguish them simultaneously.

Lots of books on Radars. Try Skolnik "Radar Handbook", try Levanon
"Radar Principles", try Kingsley and Quegan "Understanding Radar Systems."
Then start reading the published papers in the Journal of the American
Meteorological Society and the like.

I doubt a Gunnplexer from a microwave oven will work. As I recall,
it has too much phase noise for coherent detection.

You're first task is to decide what you want to measure, then
spec the system. For my radars class in grad school simply specifying
the system was the final class project. It took three of us a couple
of weeks just to nail down the specifications.

If at all possible, try to avoid having a steerable antenna. One
fixed antenna beam considerably simplifies things.

Good Luck,

Joe

Earl,
Radio Amateurs Handbook has one in it I built about 3 years ago... about
$40.00 for parts, I could squeeze 50 watts out.

Later,
Dave

> Here's an AC theory question, Tom. Do think it is possible to take
> 120V/60Hz and make 10,000V/60Hz with one capacitor and one inductor?

I received a request via e-mail to provide a solution to this problem. I
am going to use values of C and L that will produce just over 10,000VAC
just in case anybody decides to build one. Assuming a frequency of 60Hz,
connect a capacitor that has +j99 ohms of reactance (28uF) in series with
an inductor tht has -j100 ohms of reactance (0.26H). The net reactance is
-1 ohm. With 120Vrms applied, a current of 120v/1 ohm=120A flows through
the series L and C. The voltage across the capacitor is 120A*99 ohms =
11,880Vrms. The voltage across the inductor is 120A*100 ohms =
12,000Vrms. In actual practice, the ESR in the L and C would reduce the
current somewhat, depending on the Q of the components used.
.....Don't try this at home, kids, without your parents
permission.

Bi-polar proms are a one time shot. They are programed by blowing fuses within
the memory array. Eproms put a charge on a floating gate and can be erased
by UV light and reprogrammed. The bi-polar were faster in the old days by a factor
of 10 to 20 . More recent Eproms have narrowed that gap.

>There are two self-resonant points of the Oren Elliot 250 pF capacitor
>used in the AL80B

I guess my point, apparently not well made, was that the reactance appearing at the anode was high at VHF not because of the physical capacitor itself. Rather, the topology of the amplifier usually involves significant series reactance in the connections to and from the capacitor. The net effect would be to place a fairly high impedance at the anode at VHF.

This is a triumph of supposition over science since I've not measured any of my amplifiers to see just what the value is. I'm just extrapolating from what I've seen in large HF amplifiers. When we don't use vacuum variables (where it's easier to control the lead inductance) the net series reactance of the tuning capacitor connection can be quite high at VHF.

Howdy Bob --

Bird takes their customer service seriously. They're a great
corporation. Just give them a call in Solon (Cleveland) Ohio and
request an operator's manual. They will very likely send you one
cheaply or free -- just make sure to have the model number.

BTW you won't hurt your scope or counter just plug it in and go to
town.

I leave in Eagle Rock and always used the MARS repeater using high
power mobile rig. Lately I can't even make a call. You people are the
ones who are suppose to go to 222 MHz because those people got their
first. I too got intimimated with that QST, gave a call to one of MARS
people, it's phony. I wouldn't even give a damn to SCARA or whoever in
that Santiago Peak group. Oh well, Mr. Dengler, KE6TZF is Sunset Ridge
Repeater group. You're one of those people jamming. I was wondering
may be you people are getting a lot high power RF's being radiated
right in your head like those guys at 147.435? If you've been using
MARS 446.650, would this mess will make you happy? I should say 73 but
don't which is appropriate this time. May be KJ6TQ would no better...

No. The tube engineer reportedly told Foote that the damage was caused by excess grid current.

>Next Foote
> told you what that person told him verbally, and now you are telling us.

Yes. Judge Lance Ito would never allow it to be entered as evidence.

> I wonder who the source engineer was and what were his exact words were.
> Do you have a letter from him?
...no letter. The tube engineer reportedly tested the tubes and found them to be leaky. Next he cut off the anodes in a lathe so he could see the insides. He reported his findings to Mr. Foote. I confirmed the theory by inspecting the insides of kaput tubes with a microscope. Have you looked at the insides of kaput tubes with a microscope, Tom?

> You have stated:
>
> 1.) That a tube grid can not be damaged from fundamental frequency
> excitation.

Not true. In "Parasitics Revisited" I stated that grid to cathode shorts can result from over excitation at the operating frequency. A photo of a thusly damaged tube is shown. The grid to cathode shorts were caused by flakes of emissive coating being stripped off the cathode by more than twice the rated drive being applied. No evidence of gold sputtering is present. For comparison, another tube is shown with evidence of gold sputtering damage.

> 2.) That electronic protection should be removed

If the existing grid-protect switch transistor is shorted and the tube is kaput, would you conclude that the grid protection circuit worked properly, Tom?

> 3.) That resistors make good fuses, and fuses are alos good for protecting
> grids.

Not all types of resistors make good fuses. If a 0.5w-rated resistor was
in series with a 4w rated grid, which would you expect to fail first?

> 4.) That skin effect causes gold to leave before the base metal

Yes, but only if the gold is elevated above 2000 degrees F.

> 5.) That gold only leaves when it boils

Not necessarily. Water can evaporate without boiling. In a vacuum, gold
just begins to evaporate at 2000 degrees F. At atmospheric pressure it
takes more than 3500 degrees F to evaporate gold.

> All of which are untrue.

I don't think so.
>
> >However, when gold sputtering takes place at the same

> tuned
> >up correctly, an atypical event probably took place.
>
> Now let's see if I follow this, if the capaciator arcs at the same time
> the tube fails, ...snip.

No. The tube oscillates at VHF. Since the VHF energy is blocked by the
HF tank, there is virtually no VHF load, which results in high grid
current. If a VHF arc forms in the anode circuit, the arc presents a low
Z load to the anode, and the grid current decreases.

> If the PA is underloaded and excitaion remains at a high level, several
> things go on.

Some amplifiers appear to sustain VHF parasitic oscillations when they are
correctly loaded.

hi!

I'm a naive newbie and i would really appreciate it if someone could direct me to, say, a WWW page or a FAQ on designing electronic circuits that involve high frequency RF applications (i.e greater than 200,300Mhz up to the 2Ghz Range)

I've heard that a tequnique called "strip lining" is used. Can anyone explain that to me (I'm probably making an idiot of myself asking these questions)

I know that circuits dont abey "normal" laws when there are high frequency RF signals involved, adn since i only know about the "normal" rules I'm completely i the dark when it comes to designing for higher frequency RF.

Thanks very much in advance,

alan ford

> make it arc.
>
We agree on this one, Tom. I have never heard of a tune cap arcing in an
AL-80. Congrats to Denny Haad. However, I have heard about a number of
bandswitch arcs in AL80s. According to QST's Paul Pagel, N1FB, Tom Rauch
received some telephone calls from Ameritron owners regarding this problem
shortly after "Parasitics Revisited" showed a photograph of a similar,
parasitic-arced bandswitch (p.33 10/90 QST). A ham in San Diego told me
he went through two bandswitches in his AL80. There should be no reason
for bandswitch arcing. The measured breakdown of the AL80's bandswitch is
Much higher than the anode supply voltage.
During Operation Desert Storm, I received a letter from a ham/serviceman
who was running an AL80 at a MARS station somewhere in the Arabian
desert. He said that he was seeing intermittent bandswitch arcing. After
lower Q suppressors were installed, the bandswitch arcing reportedly
stopped, despite the dusty environment.

Check out the Op-Amp cookbooks and Linear Series manuals for the
following...

AN612, and TA7320P...These are quite popular in CB radios. NTE and ECG
don't have much, Motorola will have more info for you - and you can search
for their website for this info. NEC, National Semiconductor and TI also
have websites - I don't know if they would have much information for you.

TA7320P is often used as a low level modulator mixer/combiner for SSB and
AM/FM use. It has also been used as a demodulator for IF derivatives in
some radios.

AN612 is used for filtering the voice into a unity gain voltage
regulator/buffer for mixing into a precise frequency for use in band pass
crystal lattice networks for AM/FM/SSB before being passed on to the
TA7320P for final processing and mixing to get the derived frequency
selection from a standard reference and the, now-modulated, IF frequency
of audio.

Linear series reference manuals are for the pinouts and Op-Amp cookbooks
may have a schematic or two to help develop your idea from. Or cannabalize
old radio manuals for engineering schematics to help you figure out the
idea.

Good luck! Happy hunting!

Microwave ovens operate at 2450 Mhz. At this longer wavelength,
hydrometeor radar cross section decreases, see for example, Balanis -
Advanced Engineering Electromagnetics. Further, the oven may be pressed
into service for a transmitter. You still need a receiver and antenna

Alan:
At high frequencies, all PCB interconnects are modelled as transmission lines, specifically - microstrip transmission lines - hence the reference to strip lining. A microstrip transmission line is a flat ribbon conductor on a ground plane backed dielectric material. At frequencies below 1 Ghz microstrip line is relatively well behaved - there are well known equations which you can use to calculate the transmission line parameters - these parameters are derived from what is referred to as the quasi static approximation. Above 1 Ghz microstrip lines radiate, so precisely evaluating their behaviour is more difficult.
For multi layer boards, where the interconnects are embedded between layers, the transmission lines are striplines. A stripline is a ribbon sandwiched in a dielectric material with ground plane both top and bottom.
There are a number of good textbooks available for microstrip and stripline design. Pozar's "Microwave Engineeering" or Collin's "Fundamentals of Microwave Engineering" both have good illustrationsand design equations. Also, microwave CAD software can be used to evaluate the effects of the interconnects.
A good data point: .110 inch ribbon on 0.016 inch FR4 = 50 ohm transmission line
From a circuit perspective, the length of the interconnect will change the observed terminal impedance of the connected components. In the

frequency domain, impedance mismatch will result in a reduction in transferred power, the establishment of standing wave patterns on the interconnects with resulting coupling and radiation. In the time domain, multiple reflections will distort the transmitted waveforms, among other things.
I hope this short primer is helpful. email me if you have further questions

2660. need info on ICOM FL-223 filters(9 MHz)

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-06 00:00:00 UTC
From: Peter Shintani <shintani@tv.sony.co.jp>
Message-ID: <55ovon$8ed@oskgw.osk.sony.co.jp>
Source record: 101032

Hi:
I bought an FL-223 narrow ssb filter for my Icom IC -706.
I am disappointed with it's performance. Either it has poor
attenuation or there is too much blow by on the
PCB.
I took it out of my rig and measured it at work.
It is suppose to be 1.8 kHz wide at - 6 dB.
I measured it on an HP -4194A gain phase analyzer.
I had the termination impedance set at 2.2kohms for the filter
and I measured 2100 Hz for the -6 dB bandwidth. Furthermore the
absolute stop band attenuation was only 45 dB peak on the top side and
55 db peak on the lower side.

I am wondering if anyone knows of either a better 9.0115 MHz filter
that can be used in place of the FL-223 or if there is a simple way
of cascading the stock filter with the optional narrow filter or
if anyone has been successful in making a homebrew ladder filter
replacement.

Peter

snip.......

The main difference between VHF-parasitic oscillation suppressors made with nichrome and those made with silver-plated copper is the resultant Q in the anode's VHF-resonant circuit. The differerence in Q can be seen with a dipmeter. Silver-plated copper suppressors produce a sharper dip than nichrome suppressors.

Tom: Are you saying that higher VHF-Q provides better VHF dampening than lower VHF-Q?

The lossy parasitic suppressor inductor is nothing new, Tom. F. E. Handy told us about it in the 1926 and 1927 *Radio Amateurs Handbook*.

The resistance-wire VHF parasitic-suppressor inductor, recommended by Mr. F. E. Handy in the 1926 Edition of the *Radio Amateur's Handbook* sounds like the very design you are suggesting, Zack. I believe it's clever. Dipmeter tests of relative VHF-Q confirm that the idea of using resistive VHF oscillation suppressor-coils is valid. Mr. Handy said:
"The combination of both resistance and inductance is very effective in limiting parasitic oscillations to a negligible value.".

Apparently, Mr. Rauch does not agree.

Cross-posted to: rec.radio.amateur.homebrew,rec.radio.cb,sci.electronics.design,sci.electronics

About the simplest NBFM modulator that you can build is a variable capacitance modulator using a varactor diode as the active component. When properly biased, this device will give you a frequency swing of up to 7.5khz deviation (on some) which you can easily control to the desired 5khz. The device is installed at the oscillator tuning circuit and causes an increased/decreased capacitance in that tuning circuit which effectively changes the frequency of the oscillator with respect to the audio signal that is riding on top of the bias voltage.

Whew! Now! Demodulating is another problem!

Hope this shed some insight! -> Phil

>

I haven't heard of that but could give it a try with some small scraps of Duroid I have. If you're really concerned, you can maybe print your circuit on an oversized piece of board and trim the edges (Duroid cuts easily with a knife or scissors). That way the edges which are exposed to the NaOH can be trimmed off if contaminated. (I assume you're using double-clad board?)

I have been using the DATAK photoresist/developer commonly available in the USA. It is a negative-acting photoresist very similar to Kodak KPR. The developer for it definitely does not harm Duroid 5870 or 5880.

>he went through two bandswitches in his AL80. There should be no reason
>for bandswitch arcing. The measured breakdown of the AL80's bandswitch
is
>Much higher than the anode supply voltage

True so far as HV, but another false conclusion so far as RF. The voltage
breakdown can be exceeded by RF. The RF voltage in a tank can soar to
several times the HV supply when the tank is underloaded. Surely you know
that.

It is impratical to design a tank that would withstand improper loading.
The normal design process involves selecting components rated at the
highest anticipated voltage under maximum line voltage, humidity,
pressure, and operating errors expected.

Traditionally the variable capacitor is selected as the limiting device,
although I sometimes (almost exclusively now) design in a spark gap from
the tube end of the tank to chassis. The bandswitch should ALWAYS have a
much higher voltage breakdown rating than the cap or gap, because any arc
in the switch will ruin it.

Unfortunatly the voltage breakdown of the air capacitors (hence my
inclusion of a gap) varies quite a bit with the alignment and finish of
the plates. The bandswitch also varies somewhat due to burrs and sharp
edges that occasionally appear.

The failure rate of the bandswitch in the AL80 series has declined almost
to zero. In my latest design refinement, the AL80B, switch failures occur
in approximately 2/10 % of total units sold. The next level higher switch
would add $140 to the cost of every PA, to benefit 2/10% of the users.
Customers would pay $120,000 a year to reduce the total yearly failure
cost of the entire customer base by perhaps $100-200. Once the less than

perfect switch is replace, the problem disappears anyway. Nichrome is not needed, although it can help by LOWERING the operating Q of the tank on the higher bands.

Even a real estate lady couldn't sell a bigger bandswitch deal like that.

Incidentally, one design I did for Heath (the SB1000) underwent two changes that cause increased switch failures. One was they left off an ANTI-corona washer on the 160 meter padding cap contact (the absolute highest voltage part of the switch). The other is they omitted specs on the transformer that would have limited the no-load voltage (secondary ESR specs and the buck-boost primary).

The bandswitch failure rate in the SB-1000 was almost 8%, compared to 3/10% in the AL80A and 2/10% in the AL80B. The combination of pointed connections by kit builders, no corona ring, and the looser transformer voltage caused that large change!

By the way, the AL-80B wafer fit the entire SB series of PA's, and offer improved voltage ratings when properly installed. They fit most Dentrons, and GREATLY improve the voltage of those switches while reducing the number of wafers and wires needed.

Please let me know if you find any disagreement with anything I've said, so I can clarify it.

>
>
>Fred

The bulk of the reactance has to be in the suppressor with its' shunt resistance, unless the designer used some long leads.

Even so the contention was the capacitor arced from parasitics, but that is impossible with it's low reactance and the values in the PA I measured.

The AL-80B is in the low hundreds of ohms and is slightly capacitive at the anode at 175 MHz, and drops to zero J at 127MHz and again at 110 MHz where the resistor in the suppressor dominates. Below 80 MHz the tank C postion starts to have a major effect.

The transmission loss through the tube (measured on a Wiltron Network analyzer) is minimum at 81.05 (-70 dB), and maximum at 156.21 MHz (-24.2 dB), it dips again at 243.83 MHz to -28.9 dB.

Removing all suppression I can't get this particular PA to oscillate, probably because it has a new socket design that grounds each grid pin directly to a foil shield with zero length. The older PA's with ceramic sockets oscillated about 100 -120 MHz if the suppressor was removed.

In any event, if the impedance was as high as assumed the nichrome woul have no effect either unless it was a large fraction of a wavelength long! With high series reactance, the nichrome path would be an open circuit, and the distributed resistance would have no effect. There would be little current and almost no I^2 R loss.

So if the conventional suppression didn't work, neither would the nichrome.

Things aren't as bleak as described, as anyone with a RF Network analyzer, an RF Impedance Analyzer, or even a lowly MHF-259 can view. If they were, the amplifier would have more problems than suppression, it would have horrid VHF TVI. You can bet harmonic or parasitic radiation from the anode would get out !!!

In article <measures-0211960617270001@port28.vcnet.com>
> Good points, Gary. The energy just isn't there from that to boil and
>evaporate gold. // I was looking at an 8877 grid structure this
>morning. My best educated guess is that it would take between 500W and
>700W to raise the 8877 grid structure to a temperature of 2000 degrees..

From the above, and you comments on skin effect, I understood you to say
fundamental RF drive just couldn't damage the grid. Most people do not
have 500/700 watt exciters. In January 1994 QST on page 31 you state "I've
never found a grid damaged by excessive HF grid current." also "Thus
complex electronic grid-protection circuits are unnecessary."

I now understand you to say Eimac told you excessive grid current was the
cause. Are you still maintaining that it takes 500 watts to damage a grid
Eimac rates at only a few watts? If it really takes 500 watts, why isn't
the 8877 grid rated at 500 watts? Is the 8877 grid as large as the anode
in a 3-500Z? Will it stand that temperature?

Are you saying the ONLY a parasitic can supply enough current to damage a
grid?

>> I wonder who the source engineer was and what were his exact words
were.

>> Do you have a letter from him?
>...no letter. The tube engineer reportedly tested the tubes and found
>them to be leaky. Next he cut off the anodes in a lathe so he could see
>the insides. He reported his findings to Mr. Foote. I confirmed the
>theory by inspecting the insides of kaput tubes with a microscope.

So all we really know is the tubes were overheated? That's all he found?

>> 1.) That a tube grid can not be damaged from fundamental frequency
>> excitation.
>
>Not true. In "Parasitics Revisited" I stated that grid to cathode shorts
>can result from over excitation at the operating frequency. A photo of a
>thusly damaged tube is shown. The grid to cathode shorts were caused by
>flakes of emissive coating being stripped off the cathode by more than
>twice the rated drive being applied. No evidence of gold sputtering is
>present. For comparison, another tube is shown with evidence of gold
>sputtering damage.

OK, let me repeat this to be sure I understand. You postulate the Cathode can be damaged by as little as twice the rated drive power, but the lower thermal mass Grid can not be damaged by as much as 5- 20 times the rated dissipation.

An 8877 can be operated in a pulse application delivering tens of kilowatts to a load with kilowatts of drive and amperes of peak grid current without failure or damage. Yet a few watts of extra drive will overheat the catode and not the small fragile grid. That is a series of conflicting statements.

>> 2.) That electronic protection should be removed
>
> If the existing grid-protect switch transistor is shorted and the tube
is
>kaput, would you conclude that the grid protection circuit worked
>properly, Tom?

I would conclude the tube likely arced, and destroyed the protect circuit. I would conclude the PA needs more ESR in the dc supply to the anode, and better transcient protection of the overload protection device.

I would improve the PA protection, not remove its' protection.

>Not all types of resistors make good fuses. If a 0.5w-rated resistor was
>in series with a 4w rated grid, which would you expect to fail first?

Ohms law doesn't work that way Rich. Dissipation divides according to the ratio of the resistances. You also assme the thermal lag and overload time capability is the same for each device, and that overload results in immediate destruction and an open circuit.

All of that is untrue. More than that:

Even very small resistors can dissipate hundreds (and in cases thousands) of watts before failure. They have voltage ratings, and voltage rating and duty cycle sets the dissipation limits. If they open, they can still sustain an arc. The normal process of a carbon (semi-conductor) based resistor failure is the resistor ages down in resistance, reducing the protection right when you need it.

A resistor with high enough resistance to heat itself up and low enough thermal mass to fail open is called a "fuse". They use metallic elements because metal ages up in resistance with current overload, not down. The open circuit time for even special very fast fuses is in seconds. Since you claim damage is done in milliseconds or less, what good could a fuse do if you example of damage time is correct? A resistor would do even less good.

>> 4.) That skin effect causes gold to leave before the base metal
>
>Yes, but only if the gold is elevated above 2000 degrees F.

No. The heating is not caused by skin effect.The gold is on the surface, it is heated by kinetic energy. The very fact it is being struck by electrons makes gold leave the grid. Gold will disappear even if it isn't melted, let alone heated to the boiling point.

>> 5.) That gold only leaves when it boils
>
>Not necessarily. Water can evaporate without boiling. In a vacuum, gold
>just begins to evaporate at 2000 degrees F. At atmospheric pressure it
>takes more than 3500 degrees F to evaporate gold.

I see. I suppose this means water starts to evaporate at 212 degrees F at sea level. If we put an open bucket of water in a cold garage, it will still be there in spring.

The physics in your statement is incorrect. We do not need to boil something for it to evaporate. We do not even need to "melt" it.

A solid will evaporate if kinetic energy of any individual atom is sufficent to break the electrical bonds holding it in place. An electron imparting energy to the atom is an ideal source of this "evaporation".

>No. The tube oscillates at VHF. Since the VHF energy is blocked by the
>HF tank, there is virtually no VHF load, which results in high grid
>current.

But when the grid draws current, it's impedance rapidly drops. That reduces the current to equibrium, unless the feedback path is very low impedance. If the feedback path was a low impedance, the thing would oscillate all the time. So the non-oscillation until the right condition contradicts the conclusion reached that power will suddenly become many kilowatts.

>If a VHF arc forms in the anode circuit, the arc presents a low
>Z load to the anode, and the grid current decreases.

If the anode draws more current, the VHF path in the anode ALSO becomes a lower impedance and feedback is reduced.

Rich, these oscillation claims appear to be just guesses. Everything attributed to them can be explained by other much more likely causes. It's a long path from the alleged statement by Foote to this point, especially since much of the parasitic damage theory is in direct conflict to circuit analysis and physics.

The facts are:
If the load is momentarily shorted (perhaps by an antenna system failure or a loading capacitor arc) or momentary excessive overdrive (I've measured rigs like the TS940 delivering up to 300 watts of RF pulse at the operating frequency when the ALC fails to follow the envelope) tank tuning capacitor and bandswitch voltage will soar. The tube can arc, or the tank tuning cap or bandswitch can arc.

I would like to experiment with A/D and D/A audio over radio. I have an excellent Babani book on the subject but all the circuits seem to have parallel outputs. I would like some sort of modem type chip that will take the parallel signal and turn it into a data stream for TX in a narrow bandwidth. Also visa versa. Is this cheaply possible using say cellular phone type circuits or am I asking the impossible.

Maybe there is a chip that does the whole thing (audio to data stream and back).

Can anyone point me in the right direction please?

Please reply via E-mail.

This PIN diode is used as an RF switch, not a rectifier. It's
forward biased to close the switch. Now, even though the level of
RF voltage may be such that the diode is reverse biased for part of
the RF period, you don't want the diode to block. Hence, the
storage time must be (much) greater than half an RF period.

Another key spec of PIN diodes used as RF switches is the junction
capacitance in the off-state, which should be suitably low.

Check out the HamComm adapter, under $20 and does it all.

http://www.cris.com/~n9zle/hc.html

Also it works with EZSSTV

> It would seem that by shorting the ends and feeding it in the center that it would be quite easy...what am I missing?

It will work fine, provided the ladder line will stand the stress when
you tighten it between the end points. I would try to relieve that stress
by using a center support, however.

Hi and thanks for reading this.

I have built several ic and transistorised projects in the passed and I have a small collection of Heathkit, Trio and some other obscure valved RX/TX and test equipment. I would like to learn some more about the insides of these magical radios that glow in the dark.

Can anyone suggest a simple circuit using readily available/manufacturable parts?

I have access to PCB manufacture facilities, test equipment, quite a lot of old (working) assorted valves and a lot of entheusiasm. Oh yes and a 1957 ARRL Handbook that I came across might come in handy too!!

I`ll look forward to any replies,

Thanks,

Keith Stevenson.

Alas, it is arrogance of that sort that gives the profession a bad name among the public. Pretty unfortunate.

From: dgf@netcom.com
Message-ID: <dgfE0IBFq.FsF@netcom.com>
Source record: 100966

I'm having difficulty getting ahold of the folks that build the spectrum analyzer scope adapter SA500ADP. Anyway, it turns out the manual was published by "Advantage Instruments Corporation" in Carson City NV. Calls to their number yield a non-descript phone message and calls are never returned. Is anyone using this scope adapter product? Have you installed the tracking generator? Have you been able to get any help from the factory? Do you know of a distributor for their products?

I'm still trying to get the tracking generator element installed and the documentation is not accurate.

Thanx for any leads/tips/help!

> that. ...snip...

No.
However, I do know that in a 3-500Z g-g amplifier that uses a 3000V anode supply, the negative-going change in anode voltage during the conduction cycle of the 3-500Z is about 2700vp (volts peak), which coincides with the peak in anode current. At this peak, the anode to (grounded)grid voltage is about 300v. {3000v minus 300v = 2700v} When the amplifier is underloaded, the tube saturates, and the anode to grid voltage (at the anode current peak) is about 150v. In other words, the negative-going change in anode voltage is about 2850vp. It's a long way from 2850vp to the 5500v or more needed to arc the bandswitch.

Therein lies the heart of the problem. Manufacturers of amplifiers tend to assume they understand everything about amplifier theory, and that all of their customers are drooling idiots.
I get phone calls from people who experienced mysterious bandswitch arcing problems in amplifiers that were tuned up correctly. Kenwood, whose

922 bandswtich arcing problems are Much more common than is the case in the AL80..., used to tell customers that bandswitch arcing was caused by rapidly switching the bandswitch while transmitting. Yeah, right.

Tom: You still do not seem to understand that the engineer said that the
excessive grid current was apparently the result of an oscillation far
above the operating frequency.

> Are you still maintaining that it takes 500 watts to damage a grid
> Eimac rates at only a few watts? ....snip........

Tom: I was talking about the 8877 grid. The rated grid dissipation is
25w. Since there is no numerical definition of 'few', I suppose 25 will
do. The answer is yes.
I have a disassembled, kaput 8877 that has substantive gold-sputtering
damage to the grid. . I estimate that it would take at least 500w to
elevate the grid to the 2000 degrees F necessary to initiate gold
evaporation in a vacuum. However, boiling gold would require even more
heat. The burst gold bubbles on the surface of the grid indiczte that
boiling probably took place. The plethora of microscopic gold melt-balls
on the surface of cathode tell me where the gold went when it left the
grid. This failure reportedly occured in an amplifier that had been tuned
up correctly.

Isn't it just the other way around? I thought large storage led to
long recovery times which led to low frequency.

There are two types of prom, one is esentially an EPROM without the
window,and the other actually has fusible elements. The former
can be programmed as an EPROM, the latter needs more current to open
the fusible elements.

The older Bill Orr handbooks featured a number of these.
One design featured a 4CX250 driving a much larger final...
took a 0.7-watt input on the 4CX250.

Also, there was an intriguing article in Ham Radio magazine
on a non-forced-air cooled 4CX250 "QRP" amp, but I don't have the
reference for this article. You could use that schematic
with forced-air cooling and a higher Ep for a bigger bang.

Message-ID: <19961108054700.AAA19292@ladder01.news.aol.com>
Source record: 100888

Hi Rich,
In a message dated 96-11-07 12:03:17 EST, you write:

>> Denny did the AL80 that was run for less than 100 units and phased out.
>> The revamped 80, 80A, 80B were under my engineering supervision.
>
>Was the tune capacitor changed substantively between the 80 and the
80A/B?

NO.

And then I wrote the RF tank voltage can exceed the dc supply voltage by
several times when the PA is unloaded. I said:
>> breakdown can be exceeded by RF. The RF voltage in a tank can soar to
>> several times the HV supply when the tank is underloaded. Surely you
know
>> that. ...snip...
And Rich says:

>NO
> However, I do know that in a 3-500Z g-g amplifier that uses a 3000V
anode
>supply, the negative-going change in anode voltage during the conduction
>cycle of the 3-500Z is about 2700vp (volts peak), which coincides with
the
>peak in anode current. At this peak, the anode to (grounded)grid voltage
>is about 300v. {3000v minus 300v = 2700v} When the amplifier is
>underloaded, the tube saturates, and the anode to grid voltage (at the
>anode current peak) is about 150v. In other words, the negative-going
>change in anode voltage is about 2850vp. It's a long way from 2850vp to
>the 5500v or more needed to arc the bandswitch.

Your analysis is seriously flawed Rich, as it was with the skin effect and
gold, the photons, and the mechanisms surround oscillation. Let me explian
why. If you have spice you can model the PA, or with a small FET you can
breadboad it. S59A measured his SB-220 and got the same values I did
measuring one here, but let me use your example.

You overlooked a VERY simple fact. When the anode is pulled low (into
current saturation) nothing prevents the *anode* from moving lower than
the chassis or catode. If the tank, or any other external inluence would
ever try to drive the anode low, it is very easy to do (at that moment in
time). The tube is a time varying resistance, not a source. BUT IT IS A
RESISTANCE IN SERIES WITH AN INTERNAL DIODE. If the flywheel action of the
high Q tank tries to force the tank lower than zero (or even lower than
the Rp/RL divider determines), nothing stops it. Away it goes.

When the anode is negative, the tube stays cut off no matter how hard the grid cathode path is turned on. It is impossible to "turn on" the anode path when the tube has this momentary negative anode to cathode voltage.

The tank overshoot holds the anode negative, and the grid starts moving the other way (towards the direction of cut-off). When the tank starts allowing the anode to move positive, it is not loaded by the time varying anode resistance. Tube resistance, at that moment of time, is higher than the value required to match the tank (at any given moment of time the dynamic resistance of the anode has to match the E/I of the tank for maximum energy transfer. The tube loads or pulls on the tank with it's resistance, it does NOT source voltage or current).

When the tank voltage reaches it's peak, the tube is cut-off by the grid cathode bias. The tube anode will overshoot (now the grid holds the plate resistance off) and the HV at the anode will greatly exceed the supply voltage.

The tank circuit voltage can exceed the supply by a very large amount if the tank Q is high and the tank is underloaded.

> Therein lies the heart of the problem. Manufacturers of amplifiers tend
>to assume they understand everything about amplifier theory, and that all
>of their customers are drooling idiots.

Sooner or later, I knew this would turn into a manufacturers condemnation.

I suspect most manufacturers don't think customers are "drooling idiots", but they probably thing people that pretend to be knowledgeable and give customers bad advice are, hi.

If I can prove my statement, that the peak tank voltage can exceed the supply voltage by significant amounts is correct, will you appologize for your accusation of manufacturers thinking customers are idiots? Will you admit your basic knowledge of PA operation is flawed?

2702. Diplexers

Newsgroup: rec.radio.amateur.homebrew

From: Giovanni Mazzola <it9xxs@exit.it>
Message-ID: <01bbcd49$574d21c0$1318a6c2@mazzola>
Source record: 100889

I'm trying to design a diplexer to be connected between the mixer (SBL-1) and
the IF output (29 MHz) of a 6m transverter I'm going to design.

I was looking around for some literature (or software tool, better) about this
subject, but it seems it isnot a popular matter.

Any help about diplexers ? Please do not confuse it with a "duplexer", a diplexer being a particular filter that allows passing of a frequency and closing of all the others to 50 ohms (sorry for a so bad explanation... HI).

It is a very interesting subject, in my opinion.

Thanks in advance.

The idea that the tank can drive the anode to high voltages is not
logical. The engine is the amplifier tube. The tank is the flywheel.

In a previous post, did you claim that the peak anode voltage produced by
a mistuned tank could exceed several times the anode supply voltage?

Rather, the topology of the amplifier usually >involves significant series reactance in the connections to and from >the capacitor. The net effect would be to place a fairly high >impedance at the anode at VHF.

Hi Fred,

I replied once, but had some more thoughts on this. First let me clarify one thing. My point in measuring the tuning capacitor was to find out if it is possible to drive it with VHF energy and make it arc, and the answer seem to be a firm "no". The impedance is too low, at least between 60-80 MHz and 1 gHz.

You mentioned the anode. If the problem was high impedance in this area of the circuit, removing a wide low resitivity conductor and replacing it with a thin more resistive conductor would do no good at all. This is simple to analyze.

At VHF and higher, longer leads become more of a transmission line problem than simple "inductance" problems. To keep the anode impedance low, a low surge impedance is required in the line leaving the anode. That is achieved with a thick conductor, because the problem is one of maintaining the lowest possible ratio of distributed capacitance to inductance in the lead.

On the other hand, any increase in distributed resistance of the lead will increase the load impedance at the anode, which increases swing voltage available due to the time varying resistance of the anode. Adding thinner nichrome wire in the VHF path would absolutely increase the resistance and reactance (impedance) presented to the anode, and aggrivate feedback at VHF.

It would however, de-Q the circuit at HF and reduce the peak anode voltage available at the operating frequency if the tank was mistuned. That's because at lower frequencies the lead length is short, and the major effect problem is simply resistance in the path of the shunt anode capaciatnce to the resonant tank.

Generally, the goal in a RF PA is to keep all path impedances as low as possible, and place a load at the proper point. That point should load the tube optimally at the frequency where the combination of internal structure and external leads forms a resonant circuit, because that is the

frequency where the parasitic occurs.

Rich suggests using thin nichrome in the leads and in the inductance of the suppressor, we looked at the leads above and see that is a bad idea, let's look at the suppressor itself. The goal of the suppressor is to place a resistance in the VHF path between the anode and chassis. The anode lead, blocking capaciator, and plate tuning capacitor, and sheet metal form that path. We certainly all know the BOTH capacitors (tune and load) should be mounted to the same sheet metal, and that sheet metal should have a short low impedance path to the grid and input circuit.

To put the resistance in that path, we need the shunt reactance to be as high as possible across the resistance at VHF. To maintain tank Q, we want the shunt reactance across the resistance to be as low as possible. Since the primary VHF path is through the resistance (in a well designed suppressor) the Q of the suppressor coil is almost meaningless. It is the impedance of the coil, and the amount of resistance, that controls VHF and higher Q.

With nichrome, we have designed a low Q HF suppressor, with less anode loading at VHF. That would explain the improvement because it reduces HF voltage, a voltage we know CAN cause the bandswitch or tuning capacitor to arc. Lowering HF Q will make the tank soother to tune also!

The only question I have is if this change is the best way to solve problems of underloaded tanks. Remember the Q goes all over the place with the setting of the loading capacitor and the mean value of time varying shunt resistance presented by the tube. The series nichrome reduces tank Q more at low Q loading settings. We want to reduce it more at hi-Q loading settings. It sure seems a better solution would be to wind the plate choke with nichrome, placing the resistance in parallel with the anode. Q reduction would be more at high anode tank operating impedances (where we really want lower Q), rather than low ones (where we are supposed to be operating the tank).

Placing nichrome in that path, if workable, would also reduce intensity of gas arcs, a "free" additional benefit.

i've got a 1938 temco 100a transmitter that needs a plate transformer for the final.
the original transformer was replaced with one that only gives me 650- 700 volts to the plate.i need 1250 to 1500 using a center tapped full wave supply.
anyone know were i can find original parts? or where to look for suitable new parts?
also where can you get crystals for the ham bands? (160-10).
i also could use output coils for this unit. i've got a coil but it was used on 2.1mhz or 2.7mhz. but would like to get a full set. the coil i have is a plug in with a variable link coil inside the two output coils.
i have the complete engineering data for this unit and would be happy to share it with anyone who wants it.
the transmitter was used as a mobile unit for WSYR 570 AM Syracuse N.Y.from 1939 to ? w2bji was the guy who ran it.
well any info on parts or old stuff would be ice. THANKS !
ka9rle bill in madison wi.

2711. BC-375 TUNING-UNIT CAPACITORS: A GOLDMINE

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-08 00:00:00 UTC
From: fsimonds@icanect.net
Message-ID: <55vnq5$f84@news.icanect.net>
Source record: 100898

BC-375 TRANSMITTER TUNING UNIT CAPACITORS

The following information, gleaned from some obsolete US Army Tech Manual, lists the capacitor ranges of various variable capacitors found in the Tuning Units of the BC-375-E Transmitter. The part no. can be found stamped on the end plate of the "condenser." The condensers are listed according to the number of the tuning unit in which they are found. Capacitance is in uuF.

TU-	Part No.	Max	Min
5A	P-7761569P2	35	20
5A	T-7660443P6	156	20
6A	P-7761569P3	77	15
6A	T-7660443P1	116	19
7A	P-7761569P4	111	23
7A	T-7660443P2	116	19
8A	P-7761569P5	66	14
8A	T-7660443P7	81	15
9A	P-7761569P6	77	15
9A	T-7660443P3	116	19
10A	P-7761569P7	62	14
10A	T-7660443P4	116	19

In addition, each tuning unit contains two identical neutralizing capacitors; the range of these is 26-19 uuF.

These capacitors are of the highest quality, being ceramic and silver plated. Even though designed for use in WW2, the BC-375 tuning units contain a wealth of "good stuffe!" National Velvet vernier drive, standoffs, caps, thick alum panel, drawn alum case, etc., etc.

The moral: Never throw anything away!

>>> I need schematics for amplifiers using the 4cx250 tubes, any number
>>> of tubes... Any help would be greatly appreciated

Well, you didn't specify what frequency range you were interested in, and
you didn't mention your amateur callsign, if you have one, so it's a bit
difficult to specifically answer your question.

However, the Radio Amateurs Handbook, published by the American Radio
Relay League, 225 Main St., Newington, CT 06111 http://www.arrl.org
has had a number of construction articles over the years. (The Handbook
is revised/updated annually). Giving you just a schematic is short-changing
you because with high-power amplifiers, particularly at VHF and above,
the construction techniques employed are a very significant part of
the amplifier design. Telling you in a schematic that a quarter-wave
line is hanging off the plate is one thing, _showing_ you that it's a
swaged piece of copper plumbing with Teflon(R) wrapped around the anode
is quite another! Cooling techniques can be rather interesting, too...

There are other texts available, such as the "Radio Handbook" by Bill
Orr, W6SAI, published by Sams Publications, that can provide a great
deal of information as well. I'm sure other readers in the group can
add their favourite texts to the bibliography!

Rich wrote:
>You are confusing the letter with the telephone conversation.

You keep referring to a letter that says nothing, and mixing in a gold story that came to you over the telephone. We agree the letter says nothing, and you can't seem to even name the engineer that started the gold rumor. All we have is a claim someone told someone else who told you, none of which is written.

Eimac has clearly told you it is a mistake to assume the problem is parasitics. This is repeated in an extract from a official letter that appeared in QST.

Please, let's move on to technical issues. Nothing is learned from arguing hear-say.

In a message dated 96-11-08 07:00:05 EST, you write:

>The idea that the tank can drive the anode to high voltages is not
>logical. The engine is the amplifier tube. The tank is the flywheel.

I understand where yiou get that from, but that is a common misunderstanding. Thinking the tube is any kind of source will get you into theory trouble big time. Let me keep this as simple as possible, and use a class B PA as an example.

Make no mistake about it, even though it sounds colorful, the tube is not an engine or a source. It does not "push" or "supply" a single bit of power. It is a time varying resistance controlled by the grid bais. Since the anode can not conduct when it is negative with respect to the cathode, we have to include a diode. That's all the tube is. Nothing more, nothing less.

The tube anode simply gives the tank a "tug" at the right instant of time. It's like pulling a flywheel with a rope rather than a lever, it certainly can not "push" anything. Even the effect of the tug isn't instantaneous.

It takes several tugs to get the tank rolling. The RF slowly builds over several cycles, that rate being controlled by the tank Q and tube's resistance.

The only thing that keeps tank voltage from building to infinity is load resistance on the tank and conduction angle of the tube. One point most laymen don't undersatnd is the anode condution angle of the anode depends heavily on the tank impedance, not just on the grid conduction angle. If the PA is mistuned, the tank voltage is limited only by the operating Q of the mistuned tank and the much shortened conduction angle of the tube.

Contrary to your claim, I don't think anyone is a "drooling idiot" for not knowing this.
That remark will come back to haunt you, because if I were going to elevate myself to the self-proclaimed position of the best amplifier expert in the country, and write article after article explaining how a PA worked and condemning anything anyone else does, I'd make damn sure I knew how the thing worked **first**.

>In a previous post, did you claim that the peak anode voltage produced by
>a mistuned tank could exceed several times the anode supply voltage?

Absolutely.

Anyone NOT understanding this effect should never write an article explaining failure modes, because it is at the root of most operating failures in PA's.

2716. Help on transistor id

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-08 00:00:00 UTC
From: hugo@infobahnos.com
Message-ID: <5605fj$925@newsfeeder.total.net>
Source record: 100903

Hi

Can someone confirm the identification this transistor.
The side inscription reads as; T. K59 GR 9D

Checking T.K59 or K59 or GR9D independently in my NTE cross-reference hbk didn't yield anything (I think K59 is the real identifier for 3SK59 which is equivalent of ECG/NTE222 MOSFET, which is actualy what I need)

The unit I have as the exact same physical appearance as the 222, metal casing with the tab and the 4 legs.

If you conclude that what I have in hand is actualy a 3SK59, can you confirm it is leg for leg equivalent with the 222?

Finaly, is there a simple test I can make with a DVM (as for bipolar transistors) to check it, that it is nor short or open.

Many thanks for your help,

H. Caron

Could this possibly be an old Phillips or Signetics databook? "NE" is a Phillips part.

We have an LMC568, which is akin to a 567, but is made specifically for demodulating SAP/SCA/FSK *FM* subcarriers up to 500KHz.

http://www.national.com/pf/LM/LMC568.html

The datasheet is only a few pages, and there are no "AM" detectors on it.

If it is our Databook, which one is it? I don't see that circuit in the "Specific" or "Video" books or appnotes.

> JFRILEY@AIRMAIL.NET
> FREDWA8AJN@AOL.COM

The B & W 800 is wound with copper wire. Nichrome is inappropriate for use in a HV-RFC because it is too resistive. Silicone-varnish (type WL/200 degrees C), electric motor wire is excellent for use in a HV-RFC . (for a detailed discussion see *Amplifiers* on my Web site) The URL is http://www.vcnet.com/measures/
VHF parasitic oscillations rarely involve the HV-RFC. The exception is Henry amplifiers. However, if you experience a big-bang, and you discover several crispy-crittered turns of wire near the top of the choke, chances are that the choke was involved in a VHF oscillation. Connecting a vhf attenuator bead in series with the top of the choke usually helps.

Hi Fred,
I have no idea what B+W used Fred, it seems reasonable to do if the resistivity works out right. The problem is on the higher bands inductance dominates, and loading will be reduced. But at least we'd get a "free" arc surge supressor.

Hi Rich,
In a message dated 96-11-08 11:12:13 EST, you write:
>snip...
>> Eimac has clearly told you it is a mistake to assume the problem is
>> parasitics. This is repeated in an extract from a official letter that
>> appeared in QST......snip........
>
>The anonymous letter you posted on this newsgroup means zero without the
>author's name.

Pay careful attention to this Rich.

If that letter means nothing, than neither do your claims someone verbally told you the gold damage was caused by parasitics. So we agree, anything verbal means zero. We BOTH have no claim.

>To the best of my knowledge, there was no part of an 'official letter'
>from Eimac that appeared in QST.

Try reading QST again, on page 71 of September 1994. They extracted portions of a letter from Reid Brandon, Eimacs application engineer. Reid plainly stated "We do not undersatnd the reference to sudden busts of ......" and also indicted some of your modifications could be harmful.

>You have not identified who the 'entire staff' is at Eimac.

I have not, but if you get a company directory and look under engineering you will find them all. So the information is indeed available.

And you can not identify anyone who will suport your claims. But since we agreed verbal comments "means zero", we are once again on the same team.

>You have not explained why it is better for a vhf suppressor to use a high
>vhf Q inductor.

I certainly have, several times.

In a properly designed suppressor, the primary VHF path is through the resistor. The primary HF path is through the inductor. Changing the series resistance of the suppressor inductor affects Q very little, since it is primarily set by the parallel resistance and reactance values, not the low series resistance of the coil.

If you look back at my response to Fred and Gary, you will see how I outlined the behavior of the lead from the tube to the tank capacitor. This is all elementry circuit and transmission line theory.

If the line from the tube to the tuning capacitor is long enough to present a high impedance to the anode, making the line out of nichrome will make difference...but the wrong way. It will make the anode impedance at VHF higher yet! If that kead is too long, we are stuck with a high anode load impedance and high feedback.

If we make that lead thin, we will make the anode impedance higher at VHF. That's because we want minimum surge impedance (max distributed C, min distributed L) in that line.

We want a short thick lead with minimum series L and maximum distribiuted C (so long as we don't compromise minimum C in the tank too much). We want the suppressor as close to the tube as possible, with the current shifting into a proper load resistance at the worrisome frequency.

Just like with photons damaging PA's on standby, 5000 volt VHF arcs across an almost zero Z capacitor, gold boiling by skin effect, and 25 watt grids that take almost 500 watts to damage, your suppressor suggestion makes no sense when looked at carefully.

That is, it makes no sense UNLESS the arc or other damage is from HF energy caused by underloading the tank. In the case of HF mis-tuning, lowering the HF Q will help the system. Lower HF Q will make the PA smoother to tune and less prone to arcing.

The crummiest tank coils give us an amp that tunes the smoothest, and arcs the least when mistuned. The grid current soars less when out of a poor tank is underloaded. I suspect the thin lossy nichrome leads in the HF signal path acomplish exactly what's done by using poorer Q tank components.

But your marketing is better. No one would buy a low Q HF tank. It'd never catch on, even if it cured problems.

2723. Re: AM detector using PLL

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-08 00:00:00 UTC
From: Michael Black <blackm00@libertel.montreal.qc.ca>
Message-ID: <Pine.SGI.3.91.961108234814.26971A-100000-100000-100000@ban.libertel.montreal.qc.ca>
Source record: 100910
Cross-posted to: sci.electronics.design,rec.radio.amateur.homebrew

But the 567, commonly used as a tone decoder, is a synchronous detector.
It has the PLL, and a separate product detector. The only question, of
course, is whether or not the method added to give a high or low output
for the detected tone can be worked around to get a linear output.

It's been a while since I've looked in the old Signetics application
book for the section on PLL's. SOmebody might have already worked on this.

The Signetics line of PLL's, which somewhere along the way got old
(I can remember when they were featured in the ham magazines as
the latest thing), did include devices with the additional product
detector (with a circuit that looks a lot like the circuit in the
now common NE602 mixer) needed for synchronous detection of AM. The
NE560 or 561 (I forget which). You could use any in the line, by
adding an external product detector. Of course, this type of
synchronous detector is the basic kind. You can get much fancier.

Hi Rich,

In article <measures-07119609081300001@port19.vcnet.com>,
measures@mail.vcnet.com (R. L. Measures) writes:
>
>Tom: You still do not seem to understand that the engineer said that the
>excessive grid current was apparently the result of an oscillation far
>above the operating frequency.

Rich, first of all the Foote letter plainly says no such thing. It states your letter about parasitics was interesting, and the inside of the tube was badly overheated. The fellow assigned to answer customer letters said it was the result of an "apparent oscillation", but never said what kind, or even that it WAS an oscillation.

If I sent in some overheated tubes, with a letter saying I thought my PA oscillated, they would most likely write back, "your tubes are cooked, apparently the result of oscillation". If I wrote a letter saying my tubes were overdriven, they would very likely reply "your tubes were apparently overdriven".

Fiind a tire with a broken belt, and take it to the tire store and tell them you think it was damaged hitting a curb, and they'll say "yep, you apparently hit a curb".

This letter should be a long dead issue. Eimac has told you directly, and indirectly through QST, if anyone implied parasitics were the cause of grid damage they were mistaken. Their view is on page 71 of the September 1994 QST, and again page 74. Eimac's official response directly disputes your claims about the grid.

>> Are you still maintaining that it takes 500 watts to damage a grid
>> Eimac rates at only a few watts? ....snip........

>Tom: I was talking about the 8877 grid. The rated grid dissipation is
>25w. Since there is no numerical definition of 'few', I suppose 25 will
>do. The answer is yes.

Let's apply some common sense.

The grid has much less thermal mass than the cathode. The more massive cathode is heated to 750+ C with 50 watts. But the smaller thermal mass grid, rated at 25 watts by the manufacturer, with gold that becomes completely liquid at 1063 C, isn't damaged until 500 watts dissipation is reached.

I'd like to find some merit in something you say, but every aspect of your postulations runs contrary to common sense and known facts (if you have a copy of Reference Data for Radio Engineers or Electronic Designers Handbook you can look the facts up). Can you explain your theory better?

73 Tom

No, not at all. They have less gain than Eimac's 3-500 as a general rule,
but all in all the gain is so close no one would notice.

This is part of the technical damages false claims of parasitics has done.
The Chinese tubes, like all tubes, arc over from gas, not parasitics.

The problem is the Chinese tubes are not pumped down properly, and the
glass to metal seals are not as reliable as they should be. QC is poorer,
and the tubes won't withstand rated operating temperatures.

Out of a batch of 100 Chinese 3-500Z's received to test, 74% arced at 6000
volts or less. 100% had bad anode connector fit, 12% had poor solder
connections in the base.

Of the 26% that marginally passed gas tests, almost 50% failed while
dissipating 500 watts in less than one hour due to seal or envelope
failure. A typical Eimac tube will run years with 500 watts of
dissipation.

>After reading about
>the effects of gas release being able to
>cause severe internal flashovers in new tubes,
>I am now wondering if there is indeed a higher
>incident of problems with the imported tubes, if
>it may be caused by contamination and poor
>quality control?

It is without a doubt gas or seal failure, yet it is wrongly blamed on
parasitics.

A similar problem happened with 8877's, Eimac had a material problem in
the heat dam causing cathode internal shorts, and people blamed it on

parasitics.

In the 1/2 Ghz and above PCB lines of a certain width, length
etc (including dielectric Cte of PCB substrate) behave as
Xmission lines/Reactance and you can design all sorts of
funny looking circuits with tracks going nowhere which are
tuned circuits, stubs etc... even gaps in the PCB become
circuits at microwaves (Slots).

QST presented years ago a technique using isolated wires
placed on a PCB to simulate microstrips. The insulation
acted as dielectric but the wires were connected to the
circuit (at least on one end!). Never tested the technique
but seemed very simple to implement. Microstrips can be
done with PCB layout tape and etching and "tuned"
with Xacto :)

TXLINE from AWR is a freebee showing how these "lines"
are designed. -> http://www.appwave.com/

There is also a good presentation of microstrip antennas
at: http://www.rfmicrowave.com

Check the following article
-> http://www.rfmicrowave.com/library/trends/aperture.htm

It will give you some insight on what can be done with
Microstrips :)

They had a freeware called PCCAD to design all sorts
of microstrip/striplines/patch&slots antennas but I can't

find it anymore on their site.

BOB:

I believe the sample port is -40dB down from the input power. Slugs for this beast tend to be rather expensive since they each cover a limited frequency and power range, but it is indeed easy to use. Just insert the slug with the arrow pointing to the antenna to measure forward power, toward the transmitter to measure reflected.

I don't know how wide a freq/power range you need or what you paid for the 43. If you find yourself looking at a big $$$ outlay for slugs, you might want to sell the 43 and look at a Telewave 44 which is wideband (30-1000 MHz) and has switches for power range and forward/reflected... no slugs needed. I've used one for about 5 years and never had a problem with it.

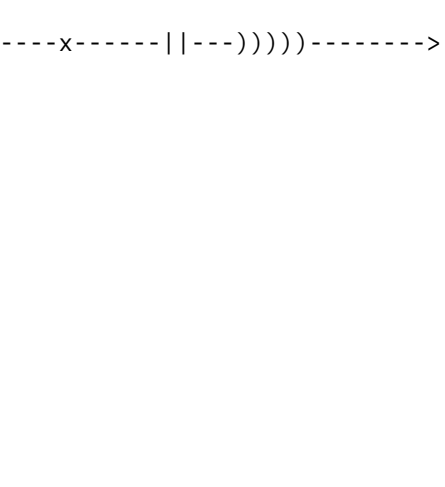
>closing of all the others to 50 ohms (sorry for a so bad explanation...
>HI).

There are several circuits called diplexers, some of them are actually
duplexers (most of the ones for combining dual band radio signals for
example). What you want is very specific, however. The circuit you need
is a bandpass between the mixer and the post amplifier and a band reject
shunting the mixer to a 50 ohm termination. The desired signal passes
through the BP filter to the post amp while not being able to reach
the termination because of the band reject filter. All other mixer
products are barred from entering the post amp by the BP filter while
being able to reach the termination via the band reject filter.

In other words, unlike a duplexer, this diplexer has both filters tuned
to the same frequency, the IF, but one is a pass and the other is a
stop filter. Here's a drawing.



C1 and L1 are series resonant at 29 MHz, C2 and L2 are parallel
resonant at 29 MHz. R1 is 50 ohms. You can, of course, use more
complex filters (higher order) in the bandpass and bandstop
sections if you desire, but this simple circuit is usually

sufficient.

Note that you want the bandpass components to have a high reactance compared to the mixer and post amp termination resistances at frequencies you don't want passed, IE use a low C resonant circuit. And the bandstop section should be high C to give a low impedance to signals off the IF frequency that are heading for the termination.

You can use ARRL Radio Designer to model this network and optimize the component values.

>: Can anyone here spell "nonlinear", or "distortion"??

Can anyone spell "industry standard"? The use of a varactor to modulate
the oscillator is the standard way NBFM radios are modulated. Motorola
has used the technique for decades, as have most of the other manufacturers.
A properly selected and biased varactor is very linear in its response
across the center of its tuning range. Of course it is biased to operate
precisely in that most linear area.

The other major technique, used in the bad old days before varactors,
isn't really FM modulation at all. It is PM, phase modulation, in a
follower stage (called a reactance modulator) after the oscillator.
The output of a PM modulator is essentially the same as the output
of a FM modulator, but with an added 6 db per octave pre-emphasis.
The standard varactor FM modulator does not inherently add pre-emphasis,
so an external pre-emphasis network is used to allow PM and FM radios
to interoperate. Note that PM can't reproduce DC as a fixed shift in
frequency, but a true FM modulator can. This can be important in data
transmission but is of no concern with speech.

Now PM can't achieve the deviation that direct FM can, so there
are usually several stages of multiplication after the PM modulator
to bring the signal on frequency and achieve the required deviation.
Varactor modulation can use this too, with the varactor moving a
crystal oscillator only a small amount, say 277 Hz, and then
multiplying up to operating frequency. A 18x multiplication will
give 5 kHz deviation for example. But a varactor modulator can
also be used directly on frequency because it can offer much
greater deviation than a PM modulator. In fact, all PLL radios
use a varactor as the control element of the on-channel VCO,
which for a 2m radio has a tuning range of at least 4 MHz, just
from varying the varactor voltage. Modulation is inserted into

the error loop of the PLL.

Incidently, the error loop filter kills DC response for this style
of radio too, so use of PLL radios for data can be a problem. That's
why a varactor modulated crystal controlled radio is preferred for
9600 baud data transmission.

> just what I was thinking. FM is most unforgiving when it comes to
>overmodulation. Even a loud voice on some FM transmitters can distort to
>the point of unintelligibility.

This is a receiver artifact and not a transmission problem. When
the signal goes outside the passband of the receiver IF, or exceeds
the linear range of the discriminator, severe distortion occurs.
But this distortion is *in the receiver* and not in the transmitter.
If the signal is very much over-deviated, the noise squelch amp
in the receiver sees it and can actually squelch the receiver on
voice peaks. Audio limiting is used in NBFM transmitters to avoid
causing these receiver problems (and to keep the transmitter's
modulation inside its assigned channel).

That's why you'll normally find a mic gain pot and a deviation pot
inside NBFM radios. The audio limiter is in between. By juggling
these two adjustments, you can control the onset of limiting so
that it occurs just at 5 kHz deviation for normal speech peaks.

>this?

What kind of radio, and what kind of amp?

You can use a power attenuator pad between the radio and the
amplifier, but you'll have to arrange switching to switch it
in and out of the circuit as you go from transmit to receive
so that it won't attenuate received signals too. This can be
a major pain. It's usually better to put the attenuator in
the amplifier, so the switching that is already in there can
take care of getting it in and out of circuit.

If your radio is a typical SSB radio, it will have an ALC
control line. If you feed a DC signal into that line, you
can reduce the radio's RF gain, and hence its output power.
A 9 volt battery and a pot will usually do it. Of course
you can also just turn the mic gain down since the output
of a SSB radio is a function of the amplitude of the modulating
audio. (If you have a speech compressor, turn it off.)

If you have a FM radio, that won't work. Many FM radios have
an internal output power adjustment, however. You can turn
the power down with this. This isn't really a modification of
the radio, just an adjustment.

>
>Finaly, is there a simple test I can make with a DVM (as for bipolar
>transistors) to check it, that it is nor short or open.

You can check an enhancement mode FET by connecting the DVM leads
to source and drain (observe polarity), and then connect the gate to
the drain with a resistor. If the transistor is good it will start to
conduct. Note, with a DVM you may have to use the diode test position
to get enough voltage to activate the transistor. With an older VOM,
just use a low ohms scale. This is a simple go/no-go functional test
that'll work on NPN bipolar transistors too.

Note the bit about observing polarity. With many meters on ohms
scale, the red probe outputs a negative voltage, not positive as
you might assume. Check your meter (with another meter naturally)
to determine if this is true for your meter. Then *write it down*
on a tag and attach it to the meter. This will save lots of frustration
later on when you're checking transistors.

Seems to me that if it's NBFM, the least of their problems would be
distortion - like who cares.. For most of the real world, the NBFM is
done by pulling the freq of a crystal before it is multiplied up to the
Xmit freq. The multiplication also multiplies the deviation.

Just curious....
Have seen several references (comments) in the
past concerning imported PA tubes, such as
the Chinese copies of Eimac's 3-500Z. I have
heard claims that these tubes are more
"prone" to VHF parasitic problems due to
their having a higher gain than the original
Eimacs.
I wonder if this is true. After reading about
the effects of gas release being able to
cause severe internal flashovers in new tubes,
I am now wondering if there is indeed a higher
incident of problems with the imported tubes, if
it may be caused by contamination and poor
quality control?

The Electret capsule used for hands-free operation of a mobile phone (it
clips on the sun-visor) can be obtained as a replacement from any mobile
radio workshop (2-way). Get the one with holes in the top _and_ a ring
of holes around the body, half way down. To power it make simple 4 volt
smoothed zennered supply for a couple of milliamps. Feed live mic lead
(+) via 2k2-6k8 from supply, and take AF output via 0.047u blocking
capacitor. Neg is ground.
They cost about ï¿½5, we've used this method. Output is about 10mv/600ohm.
PTT switch: use waterproof microswitch moulded in epoxy fixed to
handlebars with a couple of cable ties. Suggest you use very light
weight cable to connect headset and boom mic so it breaks easily if you
and the bike part company! ;-)

Hope this helps

Try checking out the Motorola CVSD chip. It was a while ago, but I thing
the numbers were
MC3417 for 3 bit version and MC3418 for 4 bit version. Look up the app
circuit in the data
book, and build it EXACTLY as shown, and you will get decent results even
with the 3 bit
version.

Dick,

Check out Moto's site at: http://www.design-net.com

You will find a wealth of info ... and many data sheets and app notes in
Adobe .pdf format for downloading ...

If you can find a copy.... Try the book " Solid State Design for the
radio amateur", published by the American Radio Relay League. It has
about a page devoted to diplexers. Lots of other good data too. If
needed, I have a link to the ARRL on my page-

Okay, this makes some sense, even though I'm not completely convinced.
It seems like if we believe that we need enough stored charge to carry
us through some part of the reverse half cycle, then as the frequency
goes up (and the period goes down) and as long as we assume that the
currents drawn are "the same," then LESS stored charge should be
required at higher voltages.

I think we're still missing something here.

The '96 Radio Amateurs Handbook has the best coverage on diplexers that I have seen. The math isn't too complex for determining component values.

The diplexer presents a fixed resistive load at all frequencies to the mixer (like 50 ohms - and this is important to proper operation of the mixer) while passing a limited range of frequencies to the following stage.

Source record: 100924

I want to clarify the comments I made about PA operation. Starting from the resting condition, assuming perfect components:

The power supply is the source, not the tube. The tube is a time-varying resistance. The dc supply charges the blocking capacitor through the high RF impedance choke. The blocking capacitor is positive on the tube side, and zero on the tank side at rest.

When the tube turns on, the high Z of the choke allows the anode to freely move around, so long as it is at a high frequency. As the tube's resistance pulls the blocking caps positive terminal towards the chassis, the end of the blocking cap that was at zero volts appears negative and this forces the tuning cap to charge negative. The resistance of the tube essentially "pulls" against the inertia of the tank capacitor through the blocking cap, as the blocking cap tries to force the tank input negative.

As tube resistance decreases, blocking capacitor voltage (and stored energy) is transferred to the tank capacitor. The RF choke also develops a strong magnetic field (it stores energy) from the power supply voltage drop across it.

The tube reaches the lowest value of resistance, it starts back up. As it starts back up the tank (since it is tuned to the same frequency) follows it. Now the field that has built up in the choke collapses, and energy is returned from the choke to the blocking cap and the tube's resistance. Since the choke is in series with the dc supply and current is diminishing, the energy stored in the choke has the same polarity as the supply, they are effectively in series. The total available voltage at the anode end of the choke is the sum of the supply voltage and the voltage developed by the collapsing magnetic field in the choke.

When the grid goes negative the tube cuts off, and the choke and power supply is free to help the blocking cap positive terminal charge positive, and this charging current helps the tank capacitor charge positive (along with the collapse of field in the tank's coil). Everything in the circuit EXCEPT the tube pushes the tank capacitor positive. All the tube can ever do is "pull" on or load the circuit. The only thing that stops this positive momentum is the tube turning back on again, and the power extracted from the tank by the load.

This mechanism can't fully charge the tank capacitance on the first few "tugs". It takes several pulls to get the tank really moving, and that depends on the tank Q, tube conduction angle, and other factors.

This process repeats over and over again. If the tank stores too much energy it tries to overshoot in the negative direction, nothing stops it.

The tube anode goes negative and the tank is free to move. Only the high RF impedance of the plate choke opposes the move towards a lower (or negative) voltage, and that isn't much opposition if the choke has enough reactance. The tube, just when we expect it to be conducting heaviest, is suddenly cut off by the negative anode voltage. The grid continues to change and tries to turn the tube back off, and by the time the anode is positive the grid has the tube cut off. The tank and choke is free to swing things up positive at the tank's freewheel rate.

When exactly matched (in step) with the tube's time varying resistance, the time varying voltage and current at the anode forms the equivalent of a source resistance. This is a non-dissipative resistance that represents the source resistance of the dc to RF conversion process. This is the resistance value conjugately matched when maximum energy conversion efficiency is desired, or maximum output under a given set of operating parameters. It can be found by a modified Fourier analysis called a Chaffee analysis (Review Science Inst. 7, October 1936). This is also a resistance very few people understand, and one that got Walt Maxwell discredited for saying what was absolutely correct.

If the tank tries to overshoot in the postive direction, the tube resistance can pull against the change, but the tube is not a low resistance at the point of maximum tank voltage. The tube is nearly cut off. It can't really put its' "resistive brake" on the positive overshoot.

The tube is also a poor positive peak voltage limiter, unless the drive level and bias places the tube well into conduction (that would only be the case in a class A PA not being driven near its' power capability).

This is why tank loading, and resistive losses in the system, primarily limit tank and anode voltage when a tank is lightly loaded. The voltage soars until equilibrium is reached with losses (including the load and tube losses) or something flashes over.

I've measured, with a class B PA operating at low (500v) voltage and a tank designed for very high voltage (~15 kV), one way peak tank voltages over FIFTEEN times the dc supply voltage when the load was shorted. You can do this at home with a high voltage FET, a 12 volt supply, a scope, and a parallel L/C load. With a MRF-150 (rated at ~150v) and a tank Q of 200, I measured almost 140 volts at the drain.

This can be verified on spice programs if the model is done correctly.

Good tank components and output devices suffer instantaneous failures almost exclusively due to this very repeatable and measurable effect. Anything lowering operating Q reduces this effect, because it loads (extracts energy) from the tank. When books indicate "pick a tank capacitor rated at two times the dc voltage" they assume the PA is correctly loaded, and giving a safe margin for minor error.

>

The Signetics application book states that the 567 has AM and FM outputs, but that they are not optimized for linear demodulation. The FM distortion is specified as 5 %. The maximum frequence for the 567 is 500 kHz.

Looking at the internal schematic diagram of the 567, the additional product detector output is available at pin 1. An external capacitor C3 is usually connected from pin 1 to ground, forming a low pass filter with an internal 4k7 resistance. Pin 1 is also internally connected to a comparator feeding the main (open collector) output at pin 8.

Reducing the capasitance of the capacitor at pin 1 to a few nF, will put the low pass filter cut-off frequency above the audio range and the demodulated AM voltage is thus available at pin 1 (pin 8 is unused).

>It's been a while since I've looked in the old Signetics application

>detector (with a circuit that looks a lot like the circuit in the
>now common NE602 mixer) needed for synchronous detection of AM. The
>NE560 or 561 (I forget which).

The NE561 has (had) an internal product detector for AM demodulation. The maximum frequency is 30 MHz (with some extension tricks up to 60 MHz).

However, I have only seen the 567 in recent years (and some 565 a few years ago) and I am afraid that the NE560-NE562 are no longer available.

>You could use any in the line, by
>adding an external product detector. Of course, this type of
>synchronous detector is the basic kind. You can get much fancier.

It is important to note that the product detector used as the phase comparator in the PLL operates at the quadrature of the AM carrier signal. The product detector used for AM detection must be run in phase with the AM carrier. Thus, there must be a 90 degree phase difference between the VCO output for the phase comparator and the VCO output for the AM demodulator.

2757. ustrip.c - Microstrip Widths

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-09 00:00:00 UTC
From: Tom Mayo N1RMU <tcmayo@fang.berk.net>
Message-ID: <328477DD.614B93BE@fang.berk.net>
Source record: 100926

Here is a C program I wrote to calculate the impedence of a microstrip given the width. I wrote it to solve a particular problem I am working on, but it could be modified to work with different parameters. It is based on an application note marked RT 3.1.2 which was given to me by a friend, so I don't know how he got it, but it was written by Rogers Corporation.

Rogers Corporation
Microwave and Circuit Materials Division
100 S. Roosevelt Ave.
Chandler, AZ 85226

602-961-1382
602-961-4533 (FAX)

I don't intend this to be a fancy program, it just implements the formulas.

If anyone sees any glaring errors, let me know and I will fix them.

Tom.

Yes, they do have a higher mu than the Eimac 3-500Z, but the mu is similar
to Amperex 3-500Z . However, most of the vhf parasitic oscillation
problems I hear about involve Chinese 572Bs, which appear to have much
higher vhf gain than do Cetron and RCA 572Bs. More gain isn't necessarily
better, unless you are trying to build an oscillator. Have you ever been
in an auditorium when someone turns up the gain too high on the PA?

At first, the Chinese tubes did have a few problems---some of which were
materials-related. In time, the problems were worked out
If internal gas were the culprit, the gas would still be there after a
big bang. I test tubes which have been removed from such amplifiers. In
most cases, the vacuums appear to be normal. For a graphite anode 3-500Z,
a normal vacuum is indicated by a leakage current of 10uA or less at at an
anode-to-grid potential of 9kV. For a metal anode 3-500Z, the normal
leakage current is 3uA or less at 9kV.

I also measure grid-to-cathode breakdown voltage (BV). Due to the bursts
of high grid current that seem to accompany parasitic vhf oscillations,
grid damage is an indication that such oscillations have occured.
For Instance, normal grid-to-cathode BV for a 3-500Z is about 8kV. For
3-500Zs that have experienced a big bang, I see reduced voltage
withstanding ability.because the hot filament is bent sideways during the
parasitic. (see photo on p.15 in Sept. 1990 QST). In some tubes, the BV

is zero volts--i.e., the grid is welded to the bent filament helices. In other tubes. the BV is reduced by a less severely bent filament. From my experiences, a 3-500Z whose grid-to-cathode voltage withstanding ability is 5kV or less, will probably develop a grid to cathode short when the tube is operated in an amplifier. Sure, 5kV sounds like plenty of BV, but when the filament is at it's normal operating temperature of 1800+ degrees K, it expands in size, reducing the grid clearance.

Cross-posted to:
rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.space,rec.radio.swap,sci.electronics.equipment

I have a copuple of PTS synthesizers for sale. These units are the 160 MHz version. Here are some of the specs:

Frequency range .100 000 MHz to 159.999 999 MHz
Resolution 1 Hz to 100KHz in decades
Accuracy 1 x 10^-8/day +/- 1 x 10^-6/0 - 50 C
Control Local by 10 position dial; remote by ttl level parallel entry BCD or GPIB

Switching time 20 to 5 microseconds
Output level +3 to 13 dBm (metered in dBm and volts)
Flatness +/- 0.5
Impedance 50 ohms
Harmonics -40dBc
Discrete spurs -75dBc

Phase Noise -63 dBc (0.5 Hz to 15 KHz) incl. effects of internal STD
100Hz/105dBc, 1KHz/115dBc, 10KHz/123 dBc,
100KHz/127 dBc
Noise Floor -135 dBc/Hz
External drive 10 MHz or 5 MHz (internal TCXO included)
Weight 35 Lbs
Mounting Rack chassis

I have scanned images of the price sheet and specs/picture sheet. These are available upon request. These units sell new (with all the included options) for over $8000. I am selling them for $500. They all have minor cosmetic scratches but are in full working condition. If interested please e-mail me at:

Greetings, I have the following items up for best offer:

1-AYDEN MICROWAVE Ga As FET amp (4450B2S), SMA Connectors
1- CALIFORNIA MICROWVE OSC 52-100833-01 (-) MT5ON-213(-), 4500-5000MHZ.
4-MERIMAC coaxial variable attenuators (ASM2-15-11K), SMA Connectors.
3-MERIMAC coaxial variable attenuators (AUMP-25A),SMA Connectors.
5-Emco 20db directional coupplers,SMA Connectors.
2- KDI 10 db directional coupplers,SMA Connectors.
1-coaxial LP filter 6000MHZ,SMA Connectors.
1 NARDA power divider 4.8 GHZ (4314-2)
8-connectors N (F) to SMA (F) panel mount.
several short lengths of semi-ridgid coax with SMA (M) connectors.
Thanks for the interest. Bruce/ ND1MW shiso@ici.net

Some 'fests are better than others for this sort of thing...

There are a number of vendors who don't have too large a minimum order (or typ.
a $5 surcharge if under).... I have used Mouser Electronics and DigiKey and
find them very good. Another I have used is Hosfelt Electronics (been a
while).

Other possibilities (includes surplus vendors): DC Eclectronics, Marlin P.
Jones, All Electronics, Cumminications Concepts Inc., MCM Electronics, C & H
Sales. _Woody_

How about an attenuator? Yeh - that might be the shot!

I assume the mobile is a phone that tx's uder 3 watts. An attenuator
(Variable) should be fairly easy to construct. Have a look at the ARRL
handbook!

> single DPDT relay). Is there a problem if two separate relays do not close
> simultaneously?

The primary consideration is that Both the RF input relay and the RF output relay contacts in the amplifier be closed, and finished bouncing, BEFORE the RF input signal arrives. Some of the newer radios begin delivering RF 5mS after switching from receive to transmit. If the amplifier relays are not fully closed in less than 5mS, relay contact arcing is certain.

In Figure 7B on my Web site, an amplifier switching circuit is shown that switches in about 2mS. Also, see QST, January, 1994 "The Nearly Perfect Amplifier".

We sell a parts kit for the circuit shown, including the Matsushita 1mS RF reed relay used to switch the input, but minus the Jennings RJ1A vacuum relay, which can be obtained for about $35 from Fair Radio Sales 419-227-6573. The price of our QSK parts kit is $20, including a spare 51v, 1.5kw, voltage surge suppressor diode (D1). If you don't want a spare D1, subtract $1.50. .

True, the distortion is going to increase as the modulation index
increases. On narrow FM you'll have very little distortion, but it would
definitely be a problem if were trying to modulate a 400Khz subcarrier at
90Khz deviation.

2775. ARRL IMD MEASUREMENTS??

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-10 00:00:00 UTC
From: w6kkt@frazmtn.com
Message-ID: <3285f303.4923618@news.frazmtn.com>
Source record: 100859

Does anyone know why when the ARRL labs test, revue and publish IMD findings on new transceivers, and linear amplifiers they compare the IMD products to the sum of the two tones (PEP output of the two tones combined)? Doing the test this way makes the IMD measurements look 6db better than what they actually are (compared to commercial standards).

2776. Radar : Circuit Diagrams for building my own

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-10 00:00:00 UTC
From: Richard Weideman <richardw@realtime.co.za>
Message-ID: <32861997.3FCD@realtime.co.za>
Source record: 100860

I would like to build my own pulsed radar for a personal tracking project.

I am trying to find a source for circuit diagrams, or a kit I can assemble/cannabilise, or any other assistance.

My design constraints are:

- to be used to track a corner reflector made of aluminized foil - (mylar)
- corner reflector cube side size limit is between 1 to 2 inches / 2.5 to 5 cm
- radar range is to cover an area 150 x 150 yards / 140 x 140 metres

- the radar will be used to track the distance of the corner reflector only
- the device will need to output elapsed time between "ping" and "echo"
- no display is required
- time output feed will be fed into a PC for processing
- 3 radar devices will be used to determine location by triangulation

If anyone can give me some pointers I'd be most appreciative.

Thanks
Richard

They did in the past, but I haven't followed the situation lately. I asked about the practice back in the 1970s -- but didn't receive an answer. The preferred method is often called the "Collins method" for taking IMD readings, the tones are set to the 0 graticule, and the IMD products read directly down from that point.

Because that's the right way to do it. Unfortunately, right or nor,
it is not the standard way to do it. The international standard is to
use either of the two (equal amplitude) tones as the reference. That
makes the IMD look 6 db worse than it actually is. Dave Russel, then
of RF Comm, was on the committee that made the recommendation.
According to him, the committee couldn't get a handle on PEP so they
compromised.

Since the L.O.S.A is getting bigger I only post the index of
applications to the newsgroups and you can download the complete
L.O.S.A from the following places...

WWW:

http://www.hth.com/losa.htm

FTP:

ftp://ftp.parallaxinc.com/pub/text/losa.txt

1.0 Whats is L.O.S.A all about ?

I started to compile L.O.S.A because I know there are lots of great
ideas and many problems that are solved with the BASIC Stamp. The
main purpose of this list is to get an idea of what other people are
using their BASIC Stamps for and maybe get some inspiration or hints.

1.1 How can I contribute to this list ?

If you have done something (big or small) with the BASIC Stamp that
you are willing to tell others please use the form given below and
write a short description, nothing fancy is needed just a simple
explanation. If you have source code to share that's even better but
it's not necessary.

Visit the following Web site and fill in the contribution form...

http://www.hth.com/losa.htm

The ARRL Handbook (any recent issue) has address for parts suppliers who will honor small orders. Chapter 30 of the 1996 edition. Also there is a list at the following site:

http://oak.oakland.edu:8080/pub/hamradio/arrl/bbs/general/parts.txt

Although this is a fairly old list (1991) it will give a starting point for address, etc. I have personally dealt with All Electronics, Jameco, Mouser, JAN Crystal, Amidon, RADIOKIT and others and have had generally good luck. The only problem with some suppliers such as Mouser is the cost is generally quite high but you can find just about anything you need.

There is no right way to make a measurement, only a standard way.

If a volt is only a volt because of how they decided to measure it.

It doesn't matter how the term is defined, so long as everyone uses the same definition.

2785. Hybrids and Gunnplexer Video ckt - HELP!

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-10 00:00:00 UTC
From: mramos@originet.COM.BR
Message-ID: <199611101903.RAA15919@netra01.origin.com.br>
Source record: 100869

I got a SHW5042 hybrid from an "crashed" Motorola trunk radio. No data for this
component even at the Design-net (Motorola homepage). In one catalog I only found some case information, but no electrical caracteristics.
Any Idea? May be a MHW5042(not found too)?
I need information on PF0031 hybrid too!

Other subject: I'm looking for schemactics on video amplifier with pre-emphasis
(CCIR 525 lines, i.e. NTSC video). I did one using a FET, some RC network and
calibrated it using a domestic satellite receiver, 18MHz IF filter and a modified
Ku band LNB. The transmitter is a 10mW Gunnplexer(MAcom). May be the CCIR curve too). The idea is not to have a domestic TVRO de-emphasis as a reference.
The circuit was calibrated with a multiburst TV signal and looks OK but...

Thanks in advance.

Nowdays, most of the world generates NBFM with varactor modulators in PLL circuits. This allows radios with microprocessor controlled frequency selection.

Multiplication of the xtal frequency is a rather ancient method now.

In article <32875267.19A9@mail.teclink.net>, "Tom C. Brown, Jr." <madison@mail.teclink.net> writes:

>Tom, what letter have you been reading? The letter that Rich is
>apparently referring to says [in part] "Both have been badly overheated
>internally, the apparent result of an oscillation condition."
>"Oscillation condition"....."oscillation condition".....hmmm.... Do PA
>tubes normally oscillate? Was he referring to the tubes oscillating at
>HF? The letter says nothing about any probably cause except an
>"oscillation condition". That letter does NOT say "nothing".

The letter is pretty clear Tom. It mentions Rich wrote an interesting letter about parasitics. It says his tubes were overheated, the "apparent result" of an oscillation condtion.

Like I said before, if I sent a part back with a letter explaining how I thought my amp had an oscillation, and they relied "yep, apparently you did. Your tubes were overheated" what doe it mean? Nothing. Just the tubes were overheated.

>Also, the letter from Mr. Foote is *signed*, and we all know exactly who
>wrote it. Unfortunately, we cannot say the same for the unsigned email
>that you posted. Unless someone at Eimac has the username "XXX", then
>the true identity of the sender must have been intentionally hidden at
>some point. Why won't you tell us who wrote it? Is the author of the
>email that you quoted afraid to take responsibility for what he said?
>It looks like it at this point..... Which makes the accuracy of said
>email highly suspect. And, as I see it, the whole case against Mr.
>Foote's credibility *is* that email.

Read QST, I've outlined the page. Mr. Measures also has been verbally told, and told in correspondence, that his claims are untrue. The specifically asked to not be bothered with this more, because it is a waste of time.

Nothing described matches theory. The photons don't, the circuit analysis does not, the grid dissipation claims do not, the resistors as fuses do not, the removal of electronic overload does not, the suddent busts of energy do not fit oscillator theory, nor do the claims of tuning capacitor damage.

When almost nothing makes sense, it might be cause to consider the source unreliable.

>But.... I really think you are throwing rocks from the porch of a glass
>house on this "unnamed source" issue.

But Rich agreed with me. Read carefully, so we can get past this. I'll post what he said.

In article <measures-08119600081300001@port17.vcnet.com>, measures@mail.vcnet.com (R. L. Measures) writes:

>> >Tom: You still do not seem to understand that the engineer said that the
>> >excessive grid current was apparently the result of an oscillation far
>> >above the operating frequency.

I wrote:
>> Rich, first of all the Foote letter plainly says no such thing.
...snip...

Rich replied:
>You are confusing the letter with the telephone conversation.

So you see, he claims the oscillation far above the operating frequency comes from a verbal conversation.

>I would recommend that you either name the *person* who wrote the
>"damning email" from Eimac or stop questioning Mr. Foote's credibility.
>One of the two would seem to be indicated at this point.

QST printed enough. I recommend you look it up.

Even if the letter did say that VHF parasitics caused the failue (which it does not) Eimac has plainly denied the accuracy of such claims. For goodness sakes, let go of it. None of these parasitic claims make any sense.

This stuff isn't that complicated.

>combined)? Doing the test this way makes the IMD measurements look
>6db better than what they actually are (compared to commercial
>standards).
>73, Jesse, W6KKT

It certainly DOES make the result look 6 dB better compared to
commercial standard test methods ... I'm sure that those who place ads
in Q$T LIKE that ...

Actually, it's pretty insulting if you think about it ... they're taking
avantage of the fact that many, many of today's appliance operators are
not technically astute enought to even recognize the fact that that 6 dB
discrepancy exists ... and that's a sad statement on the state of ham
radio, too ...

It's bad enought that the advertisers are willing to try to pull this
one over on us ... it's even WORSE that the ARRL is actively
participating in the sham! (guess what, it doesn't surprise me in the
least!)

I just got the following. I CANNOT VERIFY THIS. However I
do know the
aircraft (hold F down then LOW) toggle does work.

From:
LAIRDPG@lub001.lamar.edu
Subject: Re: TH28A mods? Anyone?

Date: Sun, 16 Aug 92
19:59:26 PDT

TH28A Mods:

1) Remove the 4 screws holding
the radio together.
2) With your finger in the battery bay, separate the two
parts.
3) The inside of the keypad case has a copper RF shield. Move this shield

out of the way by removing the 2 screws and bending it up and away from
the PC
board. (There may be double sticky tape holding t
he shield to
the IC.) Under the shield you will find a large IC surrounded by

an array of diodes, as follows:

+-------+

```
| |
| IC |
| |
D D
D D +-------+
1 1 1 1

5 4 3 2

D D D D
1 1 9 8

1 0
```

(The diode numbers are read vertically.)

NOTE: Diodes D15 & D14 are
NOT present in the American version.

4) Remove diodes D8 and D10.
5) Install one of
these diodes in D14.

This enables th
e following three extended modes:

1) Extended receive from 360 Mhz to 400 Mhz.

2) Extended receive from 400 Mhz to 520 Mhz.
3) Extended transmit/receive from
136 Mhz to 174 Mhz.

in addition to the existing aircraft frequencies of:

4)
Receive from 118 Mhz to 136 Mhz. (AM)

(AM and FM are switched automatically according to the frequency range.)

To switch
between the modes, press the [F] key for one second, then
press the [LOW] key. This
will switch between:
a) Amateur VHF band (136 Mhz to 174 Mhz).
b) 340
Mhz band (340 Mhz to 400 Mhz).
c
) Aircraft band (118 Mhz to 136 Mhz).

To get the extended amateur UHF receive,
press the [BAND] key while in the
136 Mhz to 174 Mhz mode.

By
just cutting diode 9, you enable the wide band receive on UHF
(from 400-520) and from
360-400 by hitting F and LOW.

I would be caref
ul when cutting diode D10 out though, I did it
(I've done surface mount mods before)
and my row 3 keys stopped working
(MEM, 3, etc) I am positive I didn't clip the
wrong diode because I
clipped the connection leading out from the diode (you'll see
what I
mean...)

Just don't get carried away
, that's all..

>This enables the following three extended modes:
>
> 1) Extended

> 2) Extended receive from 400 Mhz to 520
Mhz.

The above is available from the diode that I mentioned above. By the way,
the
mods presented here hold some validity as they
come from a tech sheet
that I got from the dealer.. a certain big mail order company
down the states)

> 3) Extended transmit/receive from 136 Mhz to 174 Mhz.
>
>in
addition to the existing aircraft frequencies of:
>
> 4) Receive from 118 Mhz to
136 Mhz. (AM)

This mod comes from simply
holding down F and hitting LOW. If this is
all you want, don't cut anything.. I
shudder at the thought at clipping
out surface mount diodes...

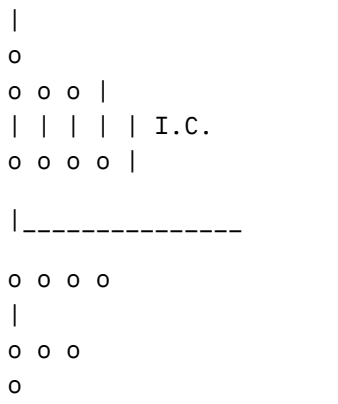
I bought a couple of TH28A's recently in the States and the guy in
the shop
did the mods for me on the spot.

The features I have on the radios are
those described by the recent
postings..

Rx AM 118.000 - 135.995
Tx/Rx FM
136.000 - 173.995
Rx FM 340.000 - 399.995
(Not 360-.. as in a previous posting)
Rx FM 400.000 - 519.995

Note: The poor
thing does not like being tuned much over 500 MHz, it beeps
at you in
complaint.

Here are the diode settings that are in my radios:



I can therefore confirm that the above freq. ranges and the above diode

settings definitely work
!!

Cheers,
Iain.

2794. NBFM modulator: design wanted

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-11 00:00:00 UTC
From: tlang@freeway.DIALix.oz.au
Message-ID: <69c_9611120701@freeway.DIALix.oz.au>
Source record: 100794
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.cb,sci.electronics.design,sci.electronics.misc

It's 09 Nov 96 21:34,
We'll return to gary@ke4zv.atl.ga.us and All's
discussion of NBFM modulator: design wanted

ga> Can anyone spell "industry standard"? The use of a varactor to
ga> modulate the oscillator is the standard way NBFM radios are modulated.
ga> Motorola has used the technique for decades, as have most of the other
ga> manufacturers. A properly selected and biased varactor is very linear
ga> in its response across the center of its tuning range. Of course it is
ga> biased to operate precisely in that most linear area.

You are indeed correct here. there are few radios using a PLL that
don't use a varactor based modulator. I do know of one or two
commercial two-ways that fit this category, but the vast majority simply
insert the audio into the main PLL loop (including Eurpean FM CB's).

ga> use a varactor as the control element of the on-channel VCO,
ga> which for a 2m radio has a tuning range of at least 4 MHz, just
ga> from varying the varactor voltage. Modulation is inserted into
ga> the error loop of the PLL.

This is the most common technique I've seen used.

ga> This is a receiver artifact and not a transmission problem. When
ga> the signal goes outside the passband of the receiver IF, or exceeds
ga> the linear range of the discriminator, severe distortion occurs.
ga> But this distortion is *in the receiver* and not in the transmitter.
ga> If the signal is very much over-deviated, the noise squelch amp
ga> in the receiver sees it and can actually squelch the receiver on
ga> voice peaks. Audio limiting is used in NBFM transmitters to avoid
ga> causing these receiver problems (and to keep the transmitter's
ga> modulation inside its assigned channel).

Indeed, if you listen to an unlimited and overmodulated FM transmission
with a wideband FM scanner, you can get some really nice audio! Doesn't
do wonders for the people on adjacent channels though. :-)

ga> That's why you'll normally find a mic gain pot and a deviation pot
ga> inside NBFM radios. The audio limiter is in between. By juggling
ga> these two adjustments, you can control the onset of limiting so
ga> that it occurs just at 5 kHz deviation for normal speech peaks.

Only problem with this arrangement is where you get two (or more) people
with widely differing voice levels. One may be hardly heard, while the
other drives the clipper so hard that the audio is grossly distorted. I
generally adjust my mike gain pot down a little to reduce distortion (I

have a tendancy to overdrive some transmitters' audio stages :)).

... Things that make you go hmmmmmmm.

I've used Protel Easytrax at home quite successfully.
It is available for free from Alberta Printed Circuits at

http://www.apcircuits.com

It is old, and kind of clunky by today's standards, but
works fine for most home-type projects.

Joe

>Gary Coffman KE4ZV | You make it, | Due to provider problems

It's more complicated than that. There is the question of
whether you do the clipping before or after the pre-emphasis.
Motorola got a patent on the technique of clipping *after*
pre-emphasis. In those days, phase modulators were used as
Gary says, and pre-emphasis was built in to the modulator.
The simplest thing was to put an audio clipper before the
phase modulator (hence before pre-emphasis). To implement
the Motorola technique, you had to 1. pre-emphasize, 2. clip
3. de-emphasize and 4. phase modulate (equivalent to FM +
pre-emphasis). Step 3 was to make step 4 look like a real
frequency modulator. You got much better "talk power", as
CB'ers would say. If I have any of this wrong, someone correct
me, but that's what we did at Konel.

In article <55iuf7$aam@newsbf02.news.aol.com>, w8jitom@aol.com (W8JI Tom)
wrote:
snip
> At 150 mA of grid current in a typical HF PA, a single 3CX800 has a
> measured grid dissipation of almost 20 watts. That's almost 5 times the
> maximum rated dissipation of the grid.

According to Eimac CURVE 005211, "Eimac 3CX800A7 Constant Current
Characteristics (Grounded Grid)":
around 27vrms of cathode-to-grid driving voltage produces the maximum
anode/plate current of 600mA.

P=I times E. 27vrms times 150mA = 4.05w(rms).

Tom: Is 4.05w "almost 20 watts" in your opinion?

Tom: If the rated grid dissipation is 4w, in your opinion is 4.05w of grid
dissipation going to increase the temperature of the grid to over 2000
degrees F, and boil the gold plating off of the grid?

> And yes, it will cause the gold to ball up, evaporate and even flake off.
> And yes, Eimac will confirm this.
>
When are you going to publish this confirmation from Eimac that supports
your position, Mr. Rauch?
--
Tom does not appear to understand what is taking place. Gold melt balls
are formed from gold vapour. I have never seen evidence of gold flaking
off the grid in a kaput tube I opened and inspected.

#Thanks!
#
#PLease EMAIL me your answers.

I was going to build a scanner using the tuner from a vcr, with a 49 Mhz
reciever for the IF. The channel circutry was going to be one of those
pushbutton tuning controls (the ones with the thumb tuned pots),which
it's control IC had an up/down control.

>
>There is no right way to make a measurement, only a standard way.

I disagree. The right way to make a measurement is the way which
gives the correct value. Any other way, whether you call it standard
or not, is the wrong way. For example, I could say that the standard
way to read the static electric field is to hold the probes of a
VOM in the air. But that would give an incorrect reading of the
static field, so it is the wrong way to make the measurement.

>If a volt is only a volt because of how they decided to measure it.

No, this is a different matter. A volt is a unit of measurement,
and units of measurement are arbitrarily defined by definition.
(Boy, is that redundant or what?) An arbitrary unit requires a
specified and arbitrary way of calibrating measuring instruments
against the standard. That's completely different from *taking*
a measurement of a parameter of interest in a circuit.

>was absolutely correct.

Hi Tom,

My understanding of Chaffee analysis is that the resistance calculated is the *load* resistance, not the source resistance. In fact, nothing is known of the source resistance (except that, in the example of a Class C amp, it is non-linear and time-varying), so how can we say there is a conjugate match?

I think this is my main hangup with the idea of "conjugate matching" to a non-linear amp such as a class C amp. The final (glowfet, fet, or bjt), is a non-linear time-varying resistance (picture a fet alternately pinched-off then wide-open - essentially a switch). How does one conjugately match a linear resistance load to a non-linear device? Does such a concept make sense?

Nothing I've read of Chaffee analysis says anything about the source resistance. The final is modeled as a non-linear current source (with *no* resistance (or, more properly, infinite resistance)). And that's it. Calculate the load resistance necessary to give the desired voltage swing, and away you go...

Regards,

- Jeff, WA6AHL

P.S. Would it be possible to get a copy of Chaffee's original article. I've always wanted to read it, but I've never found it.

>This is a nice number to commit to memory.
>
>--
>Win
>

what about this: (Bipolar transistors only)
the gain is A= g_m * R_c = I_c / U_t * R_c
The maximum value of I_c * R_c is Vcc resulting in:
A_max = Vcc / U_t, so for 12 v Vcc you can get a maximal amplification of
nearly 500.

comments?

> N6OTQ

you can not run easily a 4cx250B without forced air cooling. The heater is the problem. Eventually the ceramic base will crack. Some form of conduction cooling would be needed. Better to use one of the conduction cooled members of the same valve family.

Try HRT. Getting a circuit will be difficult except from Pye service
centres.

2821. 4cx250 glows blue-ish: what's wrong?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-11 00:00:00 UTC
From: Peter Dingemans <129432pd@mstore.eur.nl>
Message-ID: <Pine.PCN.3.91.961111150959.7898B-100000@[130.115.53.199]>
Source record: 100877

G'day everyone,

A couple of weeks ago I built an amplifier, using a (surplus) 4cx250. The problem is: it doesn't work (much). Guess the coils/cap's aren't in the band yet.

That's not the main problem, though. When I turn on the amp, you can see a blueish glow inside of the tube. It can only be noticed when it's dark, and is hard to see because of the ceramic envelope, but is definitely there. When I increase anode-current, the glow gets brighter.

I vaguely remember reading something about this a long time ago; in that article, they said it was because of poor vacuum. Could this be right, i.e. that the tube suffers from poor vacuum? Or am I guessing in the completely wrong direction, and is there a blue glow in every VHF power tube?

Hope someone has an answer to this,

Thanks in advance,

P.Dingemans,
Rotterdam,
The Netherlands.

"Because that's the right way to do it"? Can you be a bit more specific? What is the theory behind ARRLs IMD measurement interpolation? In the sixties and seventies their measurement technique coincided with every other manufacturer of commercial high power sideband transmitters,amplifiers, tubes, analyzer equipment, etc.(Collins Radio, TMC, Continental, Eimac). Somewhere along the way they adopted a more lenient (6db) measurement interpretation for their revue of new equipment. Why?

>can we say there is a conjugate match?

Because we define conjugate match as the point of maximum power transfer, because we can measure it with a reverse generator, and because resistance is defined by E/I, and that's what Chaffee gave us in his analysis..

> I think this is my main hangup with the idea of "conjugate
>matching" to a non-linear amp such as a class C amp. The final
>(glowfet, fet, or bjt), is a non-linear time-varying resistance
>(picture a fet alternately pinched-off then wide-open - essentially a
>switch). How does one conjugately match a linear resistance load to a
>non-linear device? Does such a concept make sense?

Because the tube only gives the tank a tug, so the tube is not the load or source. The source is the energy provided by the mechanics of the conversion process, and it has a optimum ration of E/I, and that is resistance.

Imagine a flwheel pushed by pistons, turning a flywheel. At a certain load impedance (rpm/torque), maximum power is coupled to the load. If we reduce the load resistance (raise the torque requirement) slightly, we will see an RPM change. The anount of load change and the amount of corresponding RPM change is the source impedance at the flywheel.

Same in the PA. Either a load pull (very slight change, so it doesn't change the conduction angle and upset the conversion process) or a backwards generator will indicate a conjugate match when the PA is tuned for maximum conversion energy transfer.

That's out of the scope of parasitics and such, so I don't want to drag it out in this thread. But the conjugate match problems, like the voltage problem many people have, comes from viewing the tube as a source. It isn't.

The power supply is the source, and the tube is a thing that converts the power supply energy (it is almost the mirror image of the explosion in a

piston engine) to a new form. Pull the load off an engine running happily at 5000 RPM and the voltage (RPM) skyrockets. Load the engine to heavily and it lugs, loses power, and overheats.

We go out of our way to overcomplicate simple processes. Models are only useful when they paint the correct picture. Thinking the tube is any kind of source is wrong.

>P.S. Would it be possible to get a copy of Chaffee's original article.
>I've always wanted to read it, but I've never found it.

I'm sure it's somewhere in original form. I no longer have access to it, but most large engineering institutions should have something.

Source record: 100882

Partial quote from Tom's message:

>>You keep referring to a letter that says nothing<<

Tom, what letter have you been reading? The letter that Rich is apparently referring to says [in part] "Both have been badly overheated internally, the apparent result of an oscillation condition." "Oscillation condition"....."oscillation condition".....hmmm.... Do PA tubes normally oscillate? Was he referring to the tubes oscillating at HF? The letter says nothing about any probably cause except an "oscillation condition". That letter does NOT say "nothing".

Also, the letter from Mr. Foote is *signed*, and we all know exactly who wrote it. Unfortunately, we cannot say the same for the unsigned email that you posted. Unless someone at Eimac has the username "XXX", then the true identity of the sender must have been intentionally hidden at some point. Why won't you tell us who wrote it? Is the author of the email that you quoted afraid to take responsibility for what he said? It looks like it at this point..... Which makes the accuracy of said email highly suspect. And, as I see it, the whole case against Mr. Foote's credibility *is* that email.

Now, as I have said before via email.....you guys are the experts here. I'm just watching and picking up lots of great info from the discussion.

But.... I really think you are throwing rocks from the porch of a glass house on this "unnamed source" issue.

I would recommend that you either name the *person* who wrote the "damning email" from Eimac or stop questioning Mr. Foote's credibility. One of the two would seem to be indicated at this point.

And thanks again for the continuing discussion......the info being batted around here is indeed extremely interesting!

Exactimundo. For biasing the output at V/2 you have G= V*20 = 240,
and if you use the entire 12V for the load resistor (almost but not
quite saturating the BJT amplifier), you get G = 500.

Blue glow is not unusual in power tubes. I have never seen voltage gain
tubes have any blue glow, just power tubes. The intensity alters with
power output. Don't worry about the blue glow... there is no such thing
as a perfect vacuum. A tube that has LOST its vacuum will not work at all
and is easily identified by a white haze or powder on the interior of the
glass bulb, near the base or the top. I believe the blue is argon gas?
Gasses sometimes are "squeezed" from the anode and the other elements during
operation. Sometimes the blue glow is very difficult to see, but I have never
seen a power tube in operation that did not have a blue glow somewhere inside.

Hi Tom-

I'm posting this here because our local ISP was offline recently while they were doing maintenance and upgrades and I missed the post (of yours) that I'm replying to......sorry about the lost message on my end.

> The letter is pretty clear Tom. It mentions Rich wrote an interesting
> letter about parasitics. It says his tubes were overheated, the "apparent
> result" of an oscillation condtion.

We agree here, Tom, the letter is clear and says basically what you've quoted above.

> Like I said before, if I sent a part back with a letter explaining how I
> thought my amp had an oscillation, and they relied "yep, apparently you
> did. Your tubes were overheated" what doe it mean? Nothing. Just the tubes
> were overheated.

I disagree here. You are putting words in Mr. Foote's mouth, and deciding what a letter that someone else wrote "really meant". That won't work. The only one who knows exactly what that letter meant is Mr. Foote.

> Read QST, I've outlined the page. Mr. Measures also has been verbally

> specifically asked to not be bothered with this more, because it is a
> waste of time.

I hear what you are saying, Tom, "read QST, read QST" and that is fine. I have the articles and will reread them when I can dig them out.

But!

You are evading a question that Rich and I have asked repeatedly, which is:

Who wrote the email that was sent by "XXX" at Eimac, that you quoted in this thread???

Please either tell us or refuse to tell us. So far, you have just evaded the question.

At this point, I'd say that you and Rich are tied at "1 to 1" in documented sources at Eimac. Your email from "XXX" would get you a 2 to 1 lead if it was not by the same Mr. Brandon who wrote for QST, *and* if you can identify the sender. At this point, you and Rich disagree, and Mr. Foote and Mr. Brandon disagree. That's a stalemate. No more, no less.

Your move.

And let me say again.....you guys are the experts here. I have done my share of work on MF PAs as big as 5 KW and VHF PAs as big as 19 KW, but I am not in y'all's league as far as designing PAs. However, I can total up the number of documented sources at Eimac that each of y'all have and see that you each have the same number of documented, *identified* sources (at Eimac) at this point.

As far as the technical issues here, I guess I'm in the middle ground.

I see what Rich is saying about a grid protection transistor being inadequate in the event of a catastrophic failure. So, I completely agree with adding fuses or "expendable resistors" and that sort of thing. I have had a half watt resistor explode and actually protect a SWEEP tube in an old amp! <g> So, that concept does work, and not just on new tubes.

But, on the other hand, I can see that the electronic grid protection circuits that have been mentioned would indeed prevent damage from some amount of mistuning and ham-fisted operation. So, while adding the brute force measures (no pun intended!) that Rich recommends, I would not remove ANY grid protection without serious cause to do so. I'd say a combination of "cataclysmic protection" and "everyday protection" would be the ticket for expensive, delicate tubes. I have seen stuff blow up in ways I wouldn't have thought possible! <g> And so have you, I suspect.....

As far as the parasitic VHF catastrophic oscillation scenario, I think it is wrong to say that EITHER it "never" happens, OR it "always" happens, when that sort of damage occurs. The fact is that in order to assess the failure mode of any given amp, the amp would have to be coaxed into failure in a controlled environment, while connected to data gathering instruments. I really think the method that I described to you via email would be the way to go. (Fast rise, storage scope in single shot mode)

Now, I don't perceive that Rich is saying that the ONLY way this sort of damage ever occurs in an amp is through parasitics......are you saying that parasitics NEVER occur? If so, then why do amps you design still have parasitic suppressors in them?

73, Tom KJ5IE

>
Check out RC (remote control) equipment. There are simple (1 transistor
with crystal control) transmitters around. I picked one up at a flea
market for next to nothing (like $1.00). Some of them use the same
circuit board and you wind different coils/transformers on the same
forms. After all, 72MHz is not that far from 50MHz. The Tx's are
"digital AM" (in mine a 1[anything over 2v] turns the TX on and anything
below that turns it off). I use a single chip ider and can either
use the output to key the TX with CW, or from the same cpu get a 1khz
sqaure wave to "AM" the Tx. (The 1KHZ is only there during a dit or dash)
Good hunting

2833. Old tube CW rigs: NETS!

From: Conard Murray <conard@tntech.campus.mci.net>
To: Multiple recipients of list <glowbugs@theporch.com>
Subject: BA/GB net hoopla!

Hi radio fans!
It was a busy Monday night on 3579.5! The band is in excellent condition with trans-contenental DX between
NA4G in North Carolina runnig a Heath HW16 and N7TM in Washington state running a Drake 2C/2NT combo.
Also worked were several stations dropping by for the first time. Stations on were:

KC5TJG/Geo in Wichita Falls, Texas
W5FRS/Dennis in Texas running a great sounding TCS (look ma, no chirp!)
W5TVW/Sandy in New Orleans running a SR150 into a Henry amp (WWL's second cousin!)
N2CQR/Bill in Va running a Halli HT37/Drake 2B
VA3RP/Rod in Ontario running a Heath DX60B
NA4G/Bob in NC with a Heath HW16
N7TM/Tom in WA running a Drake 2C/2NT combo
K4MSG/Paul in Va running (classified)
AF4K/Bry in MD running (classified)
WS4S/Conard in TN running HB 6V6->6Y6/R-390A
Also heard calling but not worked was K7FJ.

How about some of you BA/GB ops in exotic DX-lands (KH6/KL7 etc.) make some schedules with us
for a late-night session so we can work you with our flea-power rock crushers?

If you want to get in some great CW time with an excellent group of operators, here is your chance.
Come up on 3579.5 after dark with whatever you can find that radiates a signal. Wait until someone
turns it over to another op and send your call. With the onset of decent propagation on 80, even
5 or 10 watts will do fine.
73 all,

>interpolation?

I don't remember history that way, Jesse. (My mind may be going with advancing age.) The IMD products in all the early articles were always referenced to PEP output. When the international standard measurement method was adopted--because the definition of PEP couldn't be agreed on--ARRL apparently decided not to follow a procedure that was logically flawed. The flaw is simply that the amplifier, with two equal strength tones, has a Peak Output Power four times the level of either tone. The distortion products produced by that amplifier, when referred to the PEP of the amplifier, translate directly into intermodulation distortion and reflect the power output of the distortion products.

The contrary opinion holds that either way we have a test of amplifier linearity and that lower numbers mean better performance. But, in fact, certains numbers--like 30, 35, and 40--have an almost magical significance. When a spec is writen for -40 db IMD relative to either tone, the customer is really asking for an amplifier whose distortion is -46 db down. And that's a tough 6 db.

I would characterricterize my position on this as adamantine. Tom is technically correct--as he so often is. But IEC can decide that white is black and I would still see white.

Doesn't anyone care about old computers?!
Find out in the new magazine of computer history nostalgia -
"Classic Computing" magazine

Historical Computer Society
3649 Herschel Street
Jacksonville, FL 32205
Contact: David Greelish, President and Founder
E-mail: historical@aol.com
On the World Wide Web - http://www.cyberstreet.com/hcs/hcs.htm (under construction)

JACKSONVILLE, FL, November 10, 1996 Some people collect stamps, baseball cards, dolls and even cars. But did you know that there is a group for people who collect computers! This group even has some members with over fifty computers in their own private collections! The Historical Computer Society is an international user group for old computer enthusiasts (old computers and/or old enthusiasts). HCS has over thirty classic computers in it s own collection; important older machines which most people have never seen before, much less heard of, like the IMSAI, Osborne, PET and more. The Society is dedicated to preserving older and classic computer hardware, software and literature while educating and helping it s members as well as the general public. Their new quarterly magazine, Classic Computing is all about personal computer history as well as computer history in general! In only twenty short years, there is much history to be shared just about personal computers. The Society and it s magazine were started in the pioneering spirit of the early computer clubs (like the Homebrew Computer Club). Even with today s impressive technological breakthroughs in computing, that fresh, exciting, pioneering spirit doesn t seem to be a part of it all anymore. HCS hopes to rekindle some of that excitement and to share it.

Many people have fond memories of their early computing days. Never has another device evolved so rapidly as to produce nostalgic artifacts in less than a quarter of a century! Classic Computing is a forum for these people to meet and share their stories.

The Historical Computer Society intends to become the authority in the community of retired personal computers. Hundreds of old computers are thrown out everyday by Americans as junk, but HCS believes that these outmoded machines have value. HCS can help owners find answers about system operation, peripherals, software, books, magazines and service.

Classic Computing is the central forum for members and is ready to become the premier circular for information, classifieds and trading of outdated equipment, etc. New subscriptions in the U.S. are only $14 a year

or try an issue for only $3; subscriptions in Canada are $16 and $24 international. Classic Computing is sold at The Computer Museum in Boston, the American Computer Museum in Bozeman, Montana and at Smithsonian Book Stores, Washington, DC.

HCS is beginning a local meeting chapter in Jacksonville, Florida! Meet once a month with others who share in the passion. If you live in North/Central Florida or Southern Georgia and would like to attend, please write David Greelish by e-mail for more information of the first meeting.

It is Normal. It is what happend when electrons travelling at 50000
miles per second hit the anode and tube walls. The light flashes with
output power on SSB. You get x-rays of TV tubes. Best not to look at
it.

I am no expert on tubes, but I have messed about with high voltage and vacuums.

Air will, like pretty much any gas (like neon or xenon or argon), glow when 'pumped' by high voltage. Different gasses glow different colors (like neon glows read). Air is rather interesting because it will glow different colors based on it's pressure (or lack of pressure). Air can glow both blue and lavender depending on how low the pressure is.

No definite answer here... just a definite maybe... 8 }

In the past, I have conducted many commercial side band, field
specification acceptance tests. We always referenced IMD to a single
tone of two equal tones. -37 to -40 (3rd order) was the norm. Using
ARRLs method the IMD would be -42 and -46.

Eimac, Today, in their book "Care and Feeding of Power Grid Tubes"
make a point of stating (page 71); "It is NOT correct to compare one
distortion product to the sum of the two tones; that is to say, the
PEP value of the signal". (ARRLs method).

ARRLs interpolation reminds me of the EPA gas mileage on new
cars.......It looks real good.....??

>have a tendancy to overdrive some transmitters' audio stages :)).

Yeah. There are better ways to deal with this than using a simple hard clipper, though that is commonly used. The first step above a hard clipper is a soft limiter. GE used a custom hybrid to do this in their older equipment (Exec II, Mastr II). Instead of hard clipping of peaks, gain decreases as the peak is approached. This is less "harsh" than a hard clipper, but of course still introduces distortion. Today, there are several chips on the market which do this. Basically this is audio AGC with a time constant which allows gain control of individual cycles of audio.

A step up from just a soft limiter is to add a syllabic rate audio AGC system, gated to prevent background noise pumping. Commercial FM broadcast uses units like the Volumax, Audimax, Optimod, etc to process the audio prior to modulation to control deviation overshoot while trying to make any necessary distortion unobjectionable (any processing *at all* is a form of signal distortion of course). Gated

compression into a soft limiter (often in multiple bands) is at the heart of most of these units. When it is set up right, it can sound pleasing, and can handle a wide range of input levels. (When set up wrong, as many rock stations do, it just sounds *loud*, without any real dynamics at all.)

It doesn't really matter whether we use a varactor modulator or a reactance modulator or even some exotic pulse repetition rate modulator to generate the FM, we still have to control the baseband audio going into the modulator to keep the deviation within the limits of the receiver (and the law). This is the most challenging aspect of FM system design.

2853. Re: Good source for amplifier tips

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-12 00:00:00 UTC
From: w8jitom@aol.com
Message-ID: <19961112163700.LAA27866@ladder01.news.aol.com>
Source record: 100827

Hi Rich,

In a message dated 96-11-12 02:48:42 EST, you write:
>
>According to Eimac CURVE 005211, "Eimac 3CX800A7 Constant Current
>Characteristics (Grounded Grid)":
> around 27vrms of cathode-to-grid driving voltage produces the maximum
>anode/plate current of 600mA.
>P=I times E. 27vrms times 150mA = 4.05w(rms).

Rich. This is unbelievable. You have no idea how to use a constant current characteristic graph, and you are writing articles implying everyone else in the world doesn't know what they are doing!

The failure to understand simple physics, like photons or the mechanisims of heat generation are one thing, but misapplying a simple operating graph is unbelievable!

When the grid current is maximum, anode voltage is below zero in a mistuned PA. These conditions are not even plotted on the graph, because they are not obtainable in steady state conditions without destroying the tube. The graph would be five times larger, or the useful operating area would be condensed to the point it was unusable with the performance calculator overlay, if Eimac included abnormal operating ranges in the data.

You aren't even calculating the values obtained in normal operation correctly, because you are mixing peak and RMS values.

Let me give an example of one thing (out of several) you have done wrong. You assumed the average RMS grid current indicated on the meter (150 mA) is the value applied to the graph. The peak grid current is many times that value, and varies throughout the RF cycle. For over half the input RF cycle, the grid is biased out of conduction. The cathode is positive with respect to the grid, and current flow in the grid is zero.

As the cathode RF driving waveform crosses zero and exceeds the bias voltage in a negative direction, the grid slowy begins to draw current. The grid meter displays this value integrated over the entire RF cycle, so peak grid current is many many times the value you used, it is far off the curves by the time the meter reads 150 mA!

You selected 27 VRMS, even though that value is low for the cathode voltage that might be obtained in a typical properly loaded circuit, and applied it to the average RMS grid current indicated by the meter. Yet that voltage is clearly not the G-K voltage in a mistuned condition at all, since the driving impedance and grid voltage soars when anode load

impedance is raised!

Remember, negative feedback is removed when the anode load impedance is raised, cathode voltage soars. The vast majority of the exciter's power is diverted to the control grid. Since this condition is NOT indicated on a typical operation graph, the design engineer needs to measure it. The grid meter does indicate the correct effective current applied to dissipation, but your voltage figure is a factor of almost five times off.

You have probably mixed steady state impedance and average driving impedances as well.

>Tom: Is 4.05w "almost 20 watts" in your opinion?

No. Since you obviously don't understand the dynamics of a PA, the dissipation is not 4.05 watts either!

>> And yes, it will cause the gold to ball up, evaporate and even flake off.
>> And yes, Eimac will confirm this.
>>
>When are you going to publish this confirmation from Eimac that supports
>your position, Mr. Rauch?

QST already in effect did that on page 71 of the Sept 1994 issue Eimac's letter says:

"Oxide cathode tubes using focus cathode design are more easily damaged in a short time under fault conditions. Newly developed circuits are quite effective in protecting tubes from excessive grid dissipation, which can result from loss of load due to failure in the feedline, balun, or antenna."

If that alone isn't enough to support my position that improper loading can quickly damage the grid, there is more. They go on to say your grid circuit suggestions are "ludicrous" (that description also seems to fit your suggestions that photons destroy tubes in PA's that are on standby), and that they have yet to see evidence of the parasitic oscillation damage claims you make.

Let this parasitic fantasia go quietly away Rich. I have no desire to beat you into the ground technically, and you will remain unbendable no matter what evidence is presented.

The tuning capacitor measures a very low Xc over the VHF and UHF range, yet you claim it arcs from VHF energy. The anode impedance actually moves the wrong way when your suppressors are installed, yet you claim they improve things. Resistors make horrid fuses (and fuses are bad enough) yet you recommend removing electronic protection and adding resistors to protect a grid. Eimac rates a grid at 25 watts, and you say it takes 500 watts. Eimac rates a cathode at many tens of amperes of peak current, and yet you say a slight amount of overdrive damages it. You claim a parasitic can drive a tube into super energy oscillation, yet claim the same tube

flat tops when overdriven by a few percent. You claim a photon can drive a gas-less tube on standby into conduction, yet current in a gas filled geiger-muller tube is in fractions of a pico-ampere.

Everything you say contradicts science, the manufacturer of tubes, and even yourself.

Shame on the publisher for letting this stuff ever get started. I hope they've learned a lesson about technical editing. Let it die Rich, let's both do something more productive.

WOW! Thanks Gary:

I didn't realize that I was opening up such a can of worms and I have been away a few days from the group.

Firstly, I think some of the responders were missing th a point when the original poster asked for a 'SIMPLE' FM modulator.

Secondly, You are absolutely correct about the deviation levels provided by a varactor. The others have also missed the point on proper biasing of the diode to drive it to the desired result. A deviation level that falls within the receiver specifications and complies with the passband limits is perfectly do-able by any standards and is dependent on a stable and well controlled bias. In designing a varactor modulator to a specific receiver you would have to monitor this condition, but once designed in, you're done.

Thirdly, there are dozens of methods of frequency or phase modulating a carrier but none as simple as the varactor method. Unless of course the original poster wants to start playing with PLLs which can be a bear to control. Especially since there job is to fight to keep the frequency stable.

Anyhow, thanks again for the support!

That'll teach me to drop a hint and take a vacation!

Anyone have a mod to enable general coverage transmit on the TS-870S?

No, I don't plan to use it on CB! I want to use it as an RF signal
generator. I've done this with past Kenwoods (TS-430, 440, 850).

It's easy. Connect a dummy load, crank the RF Output and Carrier pots
all the way down, select AM mode, and dial up your desired frequency.
Voila... a nice stable carrier on the desired frequency, with 10 Hz
readout! Need modulation? Add some (but keep the gain real low).

So... any help on this?

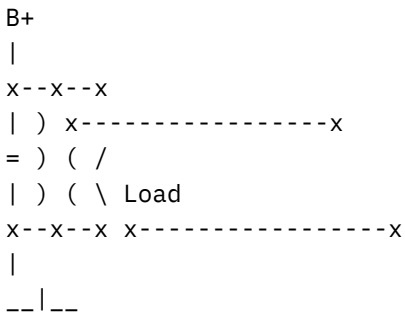
>(picture a fet alternately pinched-off then wide-open - essentially a
>switch). How does one conjugately match a linear resistance load to a
>non-linear device? Does such a concept make sense?

No, it doesn't. If you treat the power supply, driving signal, tube, and plate tank as a *unit*, you can assign the *totality* a mathematical artifact you can call source impedance, but it has very little physical reality in relation to individual components of the circuit. The limiting source impedance of *the tube* is cathode emission. We don't ever want to match that, or we'll burn up the amplifier. The source impedance of the power supply is the limit of the rectifier diodes or the transformer core saturation, or core winding resistance, whichever is greater, and we don't want to match that either. The tank isn't a source per se, nor is the driving signal, so we can't match them. Only the unity of the entire circuit can be treated as a source for the purposes of assigning it a source impedance.

What makes this talk of "conjugate matching" sometimes confusing is when the plate tank and the load impedance transforming network are combined, such as in the pi net, so that it is difficult to visualize the separate physical processes going on in the two. The physical processes are easier to visualize if we separate these functions a bit like this:



> Nothing I've read of Chaffee analysis says anything about the
>source resistance. The final is modeled as a non-linear current source
>(with *no* resistance (or, more properly, infinite resistance)). And
>that's it. Calculate the load resistance necessary to give the desired
>voltage swing, and away you go...

Right. The tube is both a current source and a valve. It valves the electrons boiling off the cathode (current source) by the action of the signal voltage on the grid (valve). This deccelerates the electrons as the grid is driven more negative and reduces the amount of current reaching the plate (closes down the valve), and vice versa. The pulses of current reaching the plate flow through the tank, drawn by the power supply potential, and complete the circuit via the power supply to the B- connection. (We get into *physical* trouble when we try to use a "conventional" current model and assume current flows from positive to negative. In a tube circuit, electrons are the majority carrier, and physical current flows from negative to positive.)

The tank is a simple harmonic oscillator tuned to some frequency. Energy "sloshes" back and forth between the capacitor and the coil, shifting energy from the electric field to the magnetic field and vice versa. Without "pushes" from the current pulses coming from the tube, the simple harmonic oscillator runs down due to losses in the tank (unloaded Q). But if the current pulses from the tube are synchronized with the tank circulating currents, and valved in just the right amount, they will make up the tank losses and a steady amount of current will circulate in the tank.

Now we add an external load. In typical RF practice, its impedance would present way too much loading on the tank, dragging loaded Q down to virtually nothing, overdamping the harmonic oscillator, and overwhelming the tube's ability to source current. So we use an impedance transforming network (shown above as a simple link transformer) to transform the impedance up to a higher value to be presented to the tank so that loaded Q stays high enough to allow the current pulses from the tube to once again stablize the circulating current in the tank at some level.

We're not "matching" to the tube, we're not "matching" to the tank, we're not "matching" to the power supply. All we're doing is *presenting* a loss of suitable value to the *unit* of tank, tube, power supply, and driving signal so that a stable and sustainable circulating tank current can be maintained while tapping off to the load as much power as the *unit* can supply to us without exceeding cathode emission limits or power supply limits or valving limits. We can *model* that as an equivalent unit "source impedance", but that's just a bit of convienent mathematical fiction which allows us to calculate circuit parameters. It has no physical reality as a real dissipative resistance, though it does have a physical reality in the tank reactances and the *virtual resistance* of the tube acting as a valve.

The behavior of *the tube* is extremely non-linear (it can be modeled as a switch in series with a diode in some cases as you note, and its resistance can be either zero or infinite). But the behavior of the *unit* is that represented by the stable circulating current in the tank. That's a smooth function for sinewave operation, and can be represented by E/I as a source impedance. We can't call it a resistance without including the cos(theta) term, however, since we are dealing with an AC signal. In the absence of a real valued load, cos(theta) is zero, and source resistance is undefined.

So your interpretation of Chaffee is correct. It is the presented real valued load impedance which, in a tangible sense, generates the mathematical artifact we call source impedance. Where people get into trouble is when they try to interpret that mathematical fiction as a real tangible resistance. It isn't. If it were, we'd be looking at a Thevenin circuit, and efficiency couldn't exceed 50% if we "matched" to the source impedance, but of course it can exceed 50% which tells us models which accept the source impedance as real valued are flawed.

sbfft11.zip Sound Blaster spectral display and filtering

Features:
* Sound Blaster 16 (or 100% compatible) input and output.
* Band widths of 2K, 4K, 8K or 16K Hz.
* Spectral resolutions of 1 Hz to 16 Hz per pixel.
* Display of power spectral density with any of 4 color maps in either
linear or logarithmic scale.
* Define and use as many as to six filters simultaneously -- band pass,
band stop, low pass, and high pass.
* Filters are defined graphically by mouse movement based upon
the displayed spectrum. Once you see a signal, you can
quickly define a pass or stop filter around the signal by clicking
and dragging the mouse.
* Net filter passband is displayed at all times.
* Filters can be selectively enabled and disabled by a single
keystroke.

Special requirements: DOS 3.0 or higher, SB16 or 100% compatible, SVGA,
VESA modes 101, 105, mouse.

2864. Sound Blaster SPectral Display & Filtering FREEWARE

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-13 00:00:00 UTC
From: kevinm@eden.com
Message-ID: <56bgf3$93j@boris.eden.com>
Source record: 100749

I have uploaded to Simtel.Net:

http://www.simtel.net/pub/simtelnet/msdos/hamradio/sbfft11.zip
ftp://ftp.simtel.net/pub/simtelnet/msdos/hamradio/sbfft11.zip 1032518 bytes

sbfft11.zip Sound Blaster spectral display and filtering

Features:
* Sound Blaster 16 (or 100% compatible) input and output.
* Band widths of 2K, 4K, 8K or 16K Hz.
* Spectral resolutions of 1 Hz to 16 Hz per pixel.
* Display of power spectral density with any of 4 color maps in either
linear or logarithmic scale.
* Define and use as many as to six filters simultaneously -- band pass,
band stop, low pass, and high pass.
* Filters are defined graphically by mouse movement based upon
the displayed spectrum. Once you see a signal, you can
quickly define a pass or stop filter around the signal by clicking
and dragging the mouse.
* Net filter passband is displayed at all times.
* Filters can be selectively enabled and disabled by a single
keystroke.

Special requirements: DOS 3.0 or higher, SB16 or 100% compatible, SVGA,
VESA modes 101, 105, mouse.

Copyrighted Freeware. Uploaded by the author.

I ran one for sometime. Never saw any glow until the amp
was operating.

What is the bias voltage on the control grid?
What is the screen voltage?
Maybe too little grid voltage lets it conduct while on standby.

4CX250's are touchy, touchy and touchy.

Anyone have any experience beefing up a 2 X 3-500Z amp? (Drake L4-B)

I'm wondering what the best power supply configuration would be for
maximum capability.

Thoughts so far are 3500V @ 1A CCS using a Dahl Hypersil.
(multi tap or variac for adjustment???)

Any insight or preferably experience would be apprieciated.

>Anyone have any experience beefing up a 2 X 3-500Z amp? (Drake L4-B)

I made a big homebrew supply for both the L-4B and L-7 amplifiers,
but my intent was to get reliable RTTY performance rather than to
increase plate voltage and resultant output. The difference in output
between running a pair of 3-500Zs at 3500 volts vs. 2500 volts just
isn't worth the cost of the parts and the additional heat generated.

The L-4B needs additional cooling air, if you run higher voltage. The
easy way is to put a muffin fan on the cabinet top, pulling air out.
The L-7 has a more efficient 2-speed cooling fan and is acceptable as-is.

The weak link in the Drake amplifiers is the voltage rating on the plate
tuning capacitor. If you boost the B+ to much more than 3000 volts and
try to tune-up into anything more than flat VSWR, you will probably
experience arcing in the tuning cap. I went back to the original Drake
power supply as the design voltages and currents are properly matched
to the rest of the RF deck. You might want to up-grade the HV rectifiers
in the Drake power supply and leave the rest original.

Try to see if the blue is on the glass surace or is inside the tube.

If on the suface then it is due to electrons striking the glass.

If inside then you have some gas in the tube and it will probably
give trouble due to incorrect grid current. I won't use a tube
that has internal gas (unless it's mercury in a rectifier).

Most commercial FM stations use a 75Khz deviation.

2880. More Grid stuff

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-13 00:00:00 UTC
From: mack@mails.imed.COM
Message-ID: <9610138479.AA847925048@mails.imed.com>
Source record: 100765

Well, I finally got through a 10 more digests. I think I'm up to 11/5 now. This topic has generated a bunch of bits!

Tom has quite correctly stated that the kinetic energy is the *primary* heat producer. This is the same effect that accounts for the lion's share of heat produced in the anode. Gary's analysis sounds good in terms of there being very little energy due to the 100 EV for each electron, but when you consider that 150 mA is a *lot* of electrons it quickly adds up! Looked at another way 150 mA into a grid at 100V is no different than 150mA into the plate of a receiving tube at 100V anode potential. Its still 15W either way.

I stand by my previous statements that it's those blasted secondary effects that have been mentioned by Tom, Ian, and Gary that are not well defined that will eat your lunch. Until we have better models we will never adequately solve these problems. Our solutions will continue to be black magic.

Ray Mack

2881. More Amplifier Stuff

Source record: 100766

Only a few more digests to go!

I wish to echo Tom's assertion that the anode voltage can soar to very high values above what is normal when it is lightly loaded. I would say what he said in a different way.

One of the things that we teach in introductory electronics is that the current through an inductor cannot make an instantaneous change in value. Any tube operating in a mode other than class A works by alternately conducting and not conducting. When the tube stops conducting the current through the plate choke continues at the same level it was when the tube quit conducting. In a properly loaded tank the impedance of the tank is a close match to the impedance of the tube and the voltage will not be affected much when the tube cuts off. However, in a lightly loaded network, the impedance can be many times higher (let's say 10 times higher). In this case as soon as the tube cuts off, the current that is flowing in the plate choke is now driving a 10 times higher impedance. This results in an immediate increase to 10 times the anode voltage.

This is a simplified example and not entirely accurate in the details, but the main point of the reason for an increased voltage remains. It's not nearly as magical as it seems.

>>No. Since you obviously don't understand the dynamics of a PA, the dissipation is not 4.05 watts either!<<

Tom, it was you who said that the grid dissipation was "about 4 watts". Not Rich.

Read back through your own postings and you will see that I am right about that.

Were you wrong then, or are you wrong now? Or is the cat both alive *and* dead? :-)

>>They go on to say your grid
circuit suggestions are "ludicrous" (that description also seems to fit your suggestions that photons destroy tubes in PA's that are on standby),
and that they have yet to see evidence of the parasitic oscillation damage
claims you make.<<

They, they, they..... WHO are "they"? So far, I have seen one, yes *one* individual at Eimac named here (by you). No more. Your use of the term "they" indicates more than one. Please supply the names of the rest of "they". Or stop saying "they".

As I said before, you and Rich are "1 to 1" in named sources so far. Why won't you tell us your sources' names? (Other than Mr. Brandon)

I'm not saying that anything you have said is wrong, but you do seem to be keeping a smoke screen between us and the identities of your sources..... And where there is smoke..... ;-)

73 and thanks again for the great discussion!

You can make a great WWV receiver by combining a converter and an auto radio. Auto radios are well shielded and make great IFs for homemade shortwave receivers. There is a schematic in our technical library at www.wenzel.com.

2888. Help with Auto Tuner Design

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-13 00:00:00 UTC
From: Kory Hamzeh <kory@avatar.com>
Message-ID: <Pine.BSI.3.91.961113165328.10755A-100000@avatar.avatar.com>
Source record: 100773

Hi Everyone,

I've decided to hack up my spare tuner, MFJ 989B, and convert it into an auto tuner. I will be using the basic stamp, a a/d convert (to get the reflected power), and three stepper motors (two for the caps, and one for the roller inductor).

I need help in the follow areas:

1. What is a good algorithm for tuning. I suspect I should set the caps in the middle position, then tune the inductor to the lowest swr and then tweak the caps & inductor back and forth several times for the lowest reading. Help!!

2. I have not idea how much torque I need to turn the caps and inductors. I have very little experience with stepper motors.

3. Any helpful hints in driving the stepper motor with the basic stamp would be great. I know a lot of this depends on the current draw which then depends on required torque. The Basic Stamp application book has an example for diving a unipolar stepper motor with a max current dram of 500 ma. Jameco also sells a little board that has a ADC and 3 stepper motor drivers. Almost perfect for what I want.

Also, I have no emotional attachments to the Basic Stamp, it just seems like the right chip to use. I am open to any other suggestions.

Thanks,
Kory

I gather that there's an experimental digital audio broadcast system defined for the VHF audio band in the UK.

You could use the same parts from CD players, but the datastream there is a minimum of 1.4 MBps. And I think the stream coming out of a digital socket on the back of a player so equipped is more than that, as they output more bits for each sample that the CD actually has along with some overhead. Parts used in computer sound cards would also be worth looking at.

Given that sort of bandwidth requirement, systems designed for over the air use will use some sort of compression, and reduced sample rates and sample sizes (compared to CD).

There may be some chips that do NICAM (the digital stereo audio system used on TV in the UK and other places in Europe). Try the Philips web site. There are decoder chips, but the system uses some sort of block compression and an encoder would be nontrivial.

Check out some articles over the past 3 or 4 years in Elektor Electronics. They've had several on NICAM, and copybit "revisers" for CD and DAT systems.

My other hobby is model rocketry and I have been flying 25 summers now, and in the winter I turn to ham radio. I would like to pull out the gear in the summer too and need the help of a Elmer. A little background first:
The National Association of Rocketry has contests through out the USA. Models that go the hightest, stay in the air the longest, scale models, and the like are how we compete. The hightest points awarded are for the R&D competion. I would like to marry ham radio and rocketry in my R&D project this year. Many have done so before, like ATV, real-time video, RDF, altimeters, etc... No one has ever work a R&D project for ground based equipment. I would like to have a wireless launch system. Many, many, many problems with a system like this. Safety would be number one. (You wouldn't want any stray RF to activate the launch system when you hooking up the rocket motor!) I need a "Elmer" to help me with this project. I don't have a EE degree, and I can use "off the shelf" equipment. So if you think you would be interested in a project like this let me know.
73 and Clear skies!

Hi,
I disagree with getting service data for Pye PMR sets, they are often
available at radio rallies, I got one for the M296 that way for 5 pounds.

Rich writes:
>I already know that the grid, anode, and cathode currents vary during the
>cycle. It is abundantly clear that this is what the constant current
>curves are all about. However, Eimac's grid dissipation rating is Not
>instantaneous watts. The grid dissipation rating is average watts.

Once again you are confused Rich. You claim understanding, and then
misconstrue results. I plainly explained you are using the correct
(indicated on the meter) RMS current, but the voltage is in error. We can
NOT use the voltage at that point of 150 mA with a positive anode voltage
on the graph, because that is not the operating point. Calculating the
true average RMS cathode RF voltage would require a set of curves far off

the graph!

If the grid is only reaching 150 mA peak on the constant current characteristic curves graph, it may very well be operating at normal or near normal values as an RF PA.

You seem to ignore the fact the cathode is in series with the PA output, and when the tank is underloaded the cathode grid voltage soars and the anode voltage at peaks goes beyond the plotted values.

>Tom: you stated that that the meter-indicated DC grid current was valid in
>such matters. Certainly, the cathode driving voltage is a sinewave, whose
>peak value is around 38v, according to Eimac's graph. The RMS value of a
>38v peak sinewave is in the neighborhood of 27v, is it not?

No. You are mis-using the curves. You are taking the peak current at one point of the operating cycle, using the cathode to grid voltage at that point with 135 volts or so of anode/grid voltage, and claiming a complete analysis. You also made the leap to a sine wave, but without a Fourier or Chaffee analysis you have no idea what the content of the waveform is.

Eimac's constant current curves do not show grossly abnormal operation, and the plot would have to include peak grid currents at least in the range of 500-600 mA down to zero under the conditions of an indicated current of 150 mA. That's because the grid cathode conduction angle is now much less than 180 degrees (and it has grid bias to overcome), and the G-K voltage increases when negative feedback is removed.

If it were a 180 degrees conduction angle sine wave in a fixed resistance, peak grid current would be (150*2.818).

Look carefully at the curves Rich. The tube is not a linear resistance as operating parameters are changed. When the grid is overdriven, the waveform squares (more higher frequency sine waves appear in the Fourier analysis). Energy content increases rapidly, and the 1.414 peak to average current and voltage ratios do not hold true. We have no idea what it is when the peak currents are far off the performance curves given.

How you can misapply this simple graph of constant current charateristics as a linear time constant resistance is fascinating. The curves plainly indicate non-linear voltage/resistance changes and great interaction between the elements of the tube.

If that isn't enough, or if it confuses you, consider this. The exciter supplying 100 watts, and with very low anode current it can't contribute to the RF output. Where does excess drive power, that used to be feedthrough power, go?

In article <328A56CD.C5A@mail.teclink.net>, "Tom C. Brown, Jr." <madison@mail.teclink.net> writes:
>

>Tom, it was you who said that the grid dissipation was "about 4 watts".
>Not Rich.

Tom, you have taken something far from context. I have no time for these little "word games". Rich plainly asked me what the grid dissipation rating of a 3CX800 was, and I replied around 4 watts. After I repeated 4 watts several tmes, he said he meant an 8877, and it was 25 watts. Let's not make this a word game debate by pulling things from the context in which they were said.

I PLAINLY stated the dissipation of the 3CX800 was just under 20 watts when the PA I was testing was mistuned to indicated 150 mA of tube grid current. Read back, rather than wasting time going over the same stuff.

>> QST already in effect did that on page 71 of the Sept 1994 issue Eimac's
>> letter says:
>
>There is no official letter from Eimac on page 71 in my copy of the
>September 1994 issue of QST. . Am I overlooking a correction or addendum
>that appeared in a subsequent issue of QST?

I guess then Rich, we will have to accept your word. As we accept your word on many other "facts":

1.) Eimac rates the 8877 grid at 25 watts, but you know it takes almost 500 watts to damage it.

2.) A geiger counter has fractions of a pico-amp in the gas filled detector tube, but a vacuum filled 3-500 can draw amperes from the same effect.

3.) Gold melts from I^2 *R heating, and not from the E*I of the element, yet that works ok for anode dissipation.

4.) Reid Brandon is not the applications engineer for power grid tubes, yet Bill Foote is.

5.) The tank capacitor has a very low Z at VHF/UHF, yet an oscillation can cause thousands of volts to appear across it

6.) Tank voltage can not overshoot when the tank is mistuned, yet even a spice analysis or a direct measurement can conform it.

7.) Tubes flat-top (power saturate) when overdriven by a few watts, yet have enough reserve to provide many kilowatts of parasitic energy

8.) Electronic overload devices need removed, yet resistors make good fuses.

9.) Eimac's constant current characteristic graph is applicable, by using one point, to calculate a PA's operating parameters.

Those are your claims.

I think this has run its' course. If you'd like to start at the beginning and discuss fundamentals, I'd be happy to spend more time. But I'm afraid without going back to basics, we will never resolve anything.

73 Tom

2897. Hybrids Information / Video Preenphasis

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-14 00:00:00 UTC
From: mramos@originet.COM.BR
Message-ID: <199611141453.MAA10066@netra01.origin.com.br>
Source record: 100691

I got two hybrids, one of them from an "crashed" trunk radio.
This is the SHW5042. I tried at the design-net site(Motorola)
but there's not any reference to this parts. Some catalogs
I have don't mention it too. May be MHW5042? The only
"empiric" information I got was some package info, since
in one Motorola books there's some items with such pin
arrange.
The other one is the PF0031, ordered at RF Parts. Unfortuna-
tely I receive the printed data to the PF0310 (it's a VHF devi-
ce).
Other subject: I did a video amplifier to an 10.25GHz Gunnplexer,
and added pre-emphasis to it. With some Jerrold TVRO satellite
receiver, worked fine, "almost" flat from 15KHz to 4.5MHz.
But I want to be shure about the correct values for a 525 line
pre-emphasis (the CCIR values). I don't want to have as a stan
dard the Jerrold de-emphasis circuit.

Any help? Thanks in advance es Best Regards.

From: gsparks@ix.netcom.com
Message-ID: <56fehk$i3j@dfw-ixnews12.ix.netcom.com>
Source record: 100692

I have decided to put together some of my junk into a CW transmitter for Straight Key Night, as well as the Morrow's I plan to use.

I found a fairly healthy transformer, a Sola model 71807, which has HV windings. I have never seen a Sola with HV before. Does anyone have the ratings of this transformer, I also still have the oil capacitor that matches it.

Is this a good choice for a HV supply, It looks a lot better than the old Zenith TV transformers I have.

Thanks in advance
Glenn Sparks KI5GY

2899. HDB3 encoding and Line Interface Chips

From: whelanj@oasys.dt.navy.mil
Message-ID: <328b3450.520389670@oasys.dt.navy.mil>
Source record: 100693

Good morning, guys. I am reverse engineering a digital communications link. I have come across a chip I cannot find (PMI LIU-01). Has anyone here had experience in the following areas to suggest a replacement?

The comm link I am working on runs 300,000 baud NRZ through a NRZ-to-HDB3 encoder and sends the three level HDB3 down a line. Got that working.

At the receive end the HDB3 is passed through a chip I cannot find, a PMI LIU-01. (I have cobbled up a fixed level recovery circuit + PLL)

PMI was bought by Analog Devices who says they are not going to continue to produce the chip and have no suggestions.

The LIU-01 chip seems to be an AGC amplifier to regulate input level, with a phase lock oscillator recovering clock from the input stream. The LIU-01 chip's output is HDB3+ and HDB3- pulses to be sent on to a decoder.

This stuff is new to me, learning along the way. Has anyone been involved in this area and might have some suggestions? Thanks,

Jerry Whelan AA3H

Howdy all.. Kc7qzr from Washington again..

I have been toying with the idea of converting my pager to ham bands, but at the moment dont want to spend the dough to get a new board for it..

Instead for experimenting with my pager, i would like to build a 931.2125mhz transmitter. (The Freq of my pager) and i have transmitter software for my pager...

I have a 2 meter transmitter built, it uses a external mic for my htx-202 handheld, midified with a 9 pin serial cord pluged into com1.. the program asks for my pagers id, then asks for the numeric message, then sends it via the com port, to the mic, it clicks the ptt, transmits the packet, and releases the ptt.. works great from what i can see.. BUT.. My pager is still in the 900mhz freq..

Any help would be MOST appreciated!!

btw my pager is a motorola renegade..

ALSO!! I am looking for another pager! any numeric or alphanumeric pager.. Dont need any documentation for it if you dont have it. Just need the pager, looking for a few of them for modification on different freq;s and bands.. May start a amateur paging service for the local hams..

THANKS A MILLION!!!!

Brad

Howdy all, Kc7qzr from Washington here....

I am still new to hamin, just got my ticket 5-17-96..!!

the only radio i have is a handheld ratshack, htx 202 2 meter ..

Its a good little radio, and i bought a external 1/4 wave antenna for it so i can use it in my truck to talk on and make autopatch calls.. it works good. but i need more than 5 watts...

Can someone help me out.. I need Very Plain Jane Schematics here.. I want to go down to radio shack, buy the needed parts and build a 2 meter amp.. If someone out there can help me out with some schematics in a very simple readable format, or can just send me what you got, and i'll get some other ham's in the area to help me with the schematics i would REALLY appreciate it!!

Please help!!

Brad

kc7qzr Washington..

p.s. I would just go buy radioshacks 35 watt amp, but its 100$ and i dont have it! and i want to learn how to do home brew stuff, so i may as well experiment a little and get my hands dirty with the nice sodering gun i bought 8-)

THANKS AGAIN!!!!!

Riccardio & the group here:
You can get a major list of sources for kits, parts, radios etc., at my web site located at:
http://www.mnsinc.com/bry/

Take a look in the ham radio resources section.
The file you need is called megalist.txt

ngaggiolir@etrurianet.it (Riccardo Gaggioli) whistled a happy tune like:

|>Hello,I need transverters(RX & TX) from 28 MHz to 144,432,1296 and upper

Folks, if you need a more reliable upto date listing of places to buy parts,
there is a file you need called megalist.txt
available at my web site:
http://www.mnsinc.com/bry/
You will find it in the HAM RADIO RESOURCES section.
Enjoy - 73 de AF4K / G3XLQ

I want to make some device able to folow radio signal in 1/4 mile

distance

if the signal is backward the receiver lit LED backward

if the signal is forward the receiver lit LED foward

if the signal is from left lit left LED

and the same for right.

some people know how to make that device.

or where can i find a documentation on this?

Somebody say is a doppler RDF receivers.

Tanks for rapid respond.

> sodering gun i bought 8-)

Brad,
I built a single transistor 2M amp a couple years ago... Unfortunately,
the parts alone cost over $100.00 without a case etc... The transistor
was $65.00... Radio shack doesn't even come close to carrying anything
needed for the amp except wire and solder.
You may find a used amp for less than $100.00, but don't count on it...
The ones I have seen were sold before the ink in the ad dried.

Later,
Dave

From: "G. Sargent" <g.sargent@auckland.ac.nz>
Message-ID: <328A4339.403E@auckland.ac.nz>
Source record: 100778

Hi All,

I am trying to find someone who sells car-alarm style remote control transmitters / receivers.

My task is to transmit an alarm indication (or, perhaps some data) with a range of approx. 60 feet.

I'm not an RF guru, so I don't know where to start...

I realise that this is not a 'proper' amature radio topic, but I have been sent here because you Guys and Gals are the experts.

Cheers,
Grant

I just found a few NOS 833a tubes hiding on a shelf. Hard to believe things this big could be hid.

I have checked all kinds of tube sale lists and have yet to find any to give me an idea of their value. Any assistance in determining an appropriate selling value would be appreciated.

Thanks,

Rob

How about a set of those remote control extenders from Radio Shack? You could wire a remote of ANY sort to the transmitter. You would have all sorts of functions then. Just a thought...
TYler

>Ray Mack

Hi Ray,

Actually there are many things going on, and both of our examples were abbreviated, hi/. I posted a longer explaination, but it is floating out in the never never land of AOL.
In any case, the huge flywheel of the tank dominates and sets the load for the choke.

I have a *long* basic language (yuk) program I wrote that calculates the voltage and other parameters, and come pretty close.

(I am really amazed that more people don't understand this stored energy effect, but when I look it isn't in many Handbooks.)

I posted the thing about voltage on a contest group, someone right away came back with "perpetum momentium" or something to that effect. Fortunately, he was receptive to measuring a PA. When he made an actual measurement, he found EXACTLY the voltage predicted for his tube type under a certain load condition...and that anode voltage went negative over a small portion of the cycle.

> data.

It seems a bit odd that Eimac does not discuss this alleged phenomenon in *Care and Feeding of Power Grid Tubes*. Certainly, in tests performed on my own amplifiers, I was unable to reproduce the incredulous peak anode voltages you said would appear during mistuning of the output network.

> You aren't even calculating the values obtained in normal operation
> correctly, because you are mixing peak and RMS values.
> Let me give an example of one thing (out of several) you have done wrong.
> You assumed the average RMS grid current indicated on the meter (150 mA) is the value applied to the graph. The peak grid current is many times that value, and varies throughout the RF cycle

. ...snip...
I already know that the grid, anode, and cathode currents vary during the cycle. It is abundantly clear that this is what the constant current curves are all about. However, Eimac's grid dissipation rating is Not instantaneous watts. The grid dissipation rating is average watts.

In a post dated 3 Nov., Mr. Rauch states:
> Don't overcomplicate grid dissipation Gary. It's given simply as the
> voltage times current at any given instant of time, and the resulting
> average value of dissipation over time. I explained the calculation. It is
> approximated by taking the average voltage grid to cathode voltage over
> the portion of the cycle when the grid is positive compared to the cathode
> (you can use a polarity sensitive and dc biased RMS RF voltmeter to
> measure this), and the average current (which is measured for you on the
> meter).

Tom: you stated that that the meter-indicated DC grid current was valid in such matters. Certainly, the cathode driving voltage is a sinewave, whose peak value is around 38v, according to Eimac's graph. The RMS value of a 38v peak sinewave is in the neighborhood of 27v, is it not?

...snip...

> No. Since you obviously don't understand the dynamics of a PA, the
> dissipation is not 4.05 watts either!

According to Tom Rauch, it should be pretty close to 4.05w.

> >> And yes, it will cause the gold to ball up, evaporate and even flake
> off.
> >> And yes, Eimac will confirm this.
> >>
> >When are you going to publish this confirmation from Eimac that supports
> >your position, Mr. Rauch?
>
> QST already in effect did that on page 71 of the Sept 1994 issue Eimac's
> letter says:

There is no official letter from Eimac on page 71 in my copy of the September 1994 issue of QST. . Am I overlooking a correction or addendum that appeared in a subsequent issue of QST?
Since we are on the subject of the unique-critique by the "recognized experts" (your words, Mr. Rauch), Paul Pagel told me that although his name was on the Technical Correspondence column in the Sept. 1994 issue of QST, he had NOTHING to do with the column. Indeed, this was unique in itself. More than a few readers came away with the impression that the unique-critique was more personal than scientific. I see that Ameritron was on your "recognized experts" list.
.....Congratulations on being recognized as an amplifier expert, Mr. Rauch.

> The letter is pretty clear Tom. It mentions Rich wrote an interesting letter about parasitics. It says his tubes were overheated, the "apparent result" of an oscillation condtion.
>
ï¿½ï¿½ RE: the "Interesting Letter" Mr. Foote refers to:

Along with the two, kaput tubes he asked me to send him, Mr. Foote requested that I note any anomalies in the amplifier. One of the more curious things I found was in the MLA-2500's VHF parasitic suppressors. I would have missed this if it hadn't been for an old-timer named 'Digger', W7MOI (RIP). Digger told me that he had seen parasitic suppressor resistors that looked perfect on the outside, but were damaged on the inside. Sure enough, the 100 ohm suppressor resistors were pristine on the outside, but their measured resistance had increased to roughly 400 ohms.

I had seen many carbon-comp resistors that became out of tolerance. The outside of such resistors typically showed signs of overheating, such a bubbling and/or cracks in the molded case, along with discolouration of the marking bands. In my opinion, something pretty strange must have happened to the suppressor resistors. Whatever it was, it must have been Potent and it must have been Quick. Since the suppressor resistors were paralleled with an inductance of less than 0.1 microHenry, which was made out of copper bus wire, it SHOULD have been pretty obvious that a DC arc or 3-30 MHz AC was not involved in damaging the resistors. When Mr. Foote told me about the oscillation condition that had been responsible for gold-sputtering damage to 8877s, the lights finally came on.

#communications receiver has an RCA plug on the back with the letters VFO above
#it. Is this Variable Frequency Oscillator? If it is, what is it used for
#exactly? Any help would be greatly appreciated. Thanks
#73 de N3SPD Tyler

RIT: Reciever incremental Tuning. This allows you to finetune your VFO
a few Khz on recieve (some radios have an XIT ,same thing on Transmit)

VFO: Variable frequency oscillator. is the main frequency control for
whatever band you are using. They are built to be rather stable as they
help determine the transmit frequency as well as the recieve.

2922. Need Help with MIC wiring

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-15 00:00:00 UTC
From: gradyr@mindspring.com
Message-ID: <gradyr-1511962130010001@user-168-121-178-82.dialup.mindspring.com>
Source record: 100638

I was wondering if any of you Homebrew Hams could help me a bit.

I have a TRC-469 CB Radio that I would like to hook up a radio shack power Mic to.

The radio's internal's is labeled Uniden.

The radio's microphone jack has 6 wires coming out. A red, black, blue, white, yellow and solid copper.

The standard microphone has an up and down button for channel changes. These are controled by wires white and black. The copper wire is the shield.

The Radio Shack power Mic has a funky DIN Plug on the end of it. With a total of 5 wires that have been identified and labeled as follows:

Wire Color Receive Transmit
==========
Copper pin #1 Shield/Ground Shield/Ground
Red pin #2 Connected to Pin #4 Floating Free
White pin #3 Floating Free Grounded to pin #1
Yellow pin #4 Connected to pin #2 Audio "hot"
Black pin #5 Grounded to pin #1 Floating Free

So the question is, what wires do I hook up the red,blue,yellow wires of the radio to? How would I go about finding out if you don't know? Learning as I go along and having a blast!

TIA,
Grady

2923. Palomar Linear

Newsgroup: rec.radio.amateur.homebrew

Does anyone have any schematics for the old Palomar tube amplifiers that CBers were using in the 70's? They were the gray box, with about 100+ watts out for 5 watts in.

I would love to get some schematics/diagrams on them, or any amp in the 100-500 watt class that takes about 5-10 watts to drive.

Another ham and I are looking to build from scratch an amplifier for 6 meter use. We were looking over the ARRL diagrams, and got on the subject of those amplifers. I recall a ham in the town where I lived got one of those amplifiers from a CBer that was getting out of the hobby in 1976, and was able to modify the input output tuning for 6 meters, and it worked great.

I would be glad to trade an official NBC 96 Atlanta Olympics poster for a set of prints. I only have 5 left. These are the 3'x2' posters they were selling for $19.95.

> Thanks much,

> Scott

Scott, first you might want to look at NIST Special Publication 432 if you
want to gain insight into the data formats used by the WWV and WWVB
services. HTMLized versions of NIST SP432 can be found at:

http://www.boulder.nist.gov/timefreq/

or http://glen-ellyn.iit.edu/~clocks/clocks/clocks.html

as an alternate site.

I'm not quite sure what you intend to do w/ a WWV/WWVB project, but perhaps
what follows will be of some help.

Since you're on Long Island, I'm not sure if WWVB reception will be
adequate for your needs...you might want do a little testing w/ a suitable
VLF receiver borrowed from a friend before going ahead w/ a WWVB project.
If you want to try a WWVB project, Don Lancaster had a pair of articles in
the August & Sept. 1973 issues of Radio-Electronics magazine describing
such a project; his project was intended to be integrated w/ his previous
Superclock III project (see the July & August 1972 issues of
Radio-Electronics) to create a self-setting digital clock. Both projects
have parts which now fall into the "unobtainium" category, so you might
want to treat Lancaster's work as more of a reference. Another WWVB
project alternative can be found in the Jan. thru March 1994 issues of 73
magazine, in a series of articles written by Bob Roehrig, K9EUI. Bob's
project is more oriented towards using the WWVB service as a means of
frequency standard calibration, but the receiver circuitry could be easily
adapted for use w/ a decoder. I've built the receiver & frequency
comparator portions of K9EUI's project, and they do work. There is another
WWVB project described in Ham Radio magazine from sometime in the
mid-'80s; unfortunately I don't have the article citation at hand.

If you want to try a WWV project, IMO the receiver portion is a snap.
Hamtronics (65 Moul Rd., Hilton NY [can't remember phone # or zip code!])

sells a crystal-controlled WWV receiver kit for I think about $60.00 which has gotten at least one positive review in the Ham radio press. An alternative would be one of the varactor-tuned SWL receiver kits sold by Ramsey Electronics (look for their ads in Electronics Now, Popular Electronics, Nuts & Volts, etc.), but I would speculate that the Ramsey receiver isn't as selective as the Hamtronics unit. Then there's always the alternative of using some used commercial SWL receiver, but it'd probably need to be dedicated to WWV reception. Decoding the WWV format is a bit more complicated than the WWVB timecode, but certainly IMO within hobbiest capabilities.

Figuring out how to deal w/ WWV or WWVB signal fading/loss may be the toughest part of the decoder design, and depending on what you want to do w/ the decoded signals you may wind up w/ a microprocessor-based solution (the old Heathkit GC-1000 "World's Most Accurate Clock" was designed around a mask-programmed 3870 microcomputer...and used a second 3870 to handle the optional RS-232 interface). Certainly it's possible to build a self-setting clock which can free run during periods of no reception w/ TTL logic gates, but a project which entails a reliable "on demand" time service via an RS-232 interface to a remote computer would be best implemented w/ some form of uP/uC/PIC.

Good luck -

TGB

)Tyler
)N3SPD

It is a noise-reduction scheme. Most of the noise in FM systems is what might be termed "high frequency" or "hiss" (similar to tape). So the high frequencies are "pre-emphasized" (i.e. get more gain than the lower frequencies). Then when played back, the high frequencies are "de-emphasized" (get lower gain). This raises the overall signal/noise ratio.

Similar schemes are used in tape decks, and on vinyl records (RIAA equalization, also called 75us equalization). Dolby is a similar scheme.

Depends on the tube, depends on the use. It's common to rebuild higher power tubes and there are companies that do it. Getters do the same basic thing with various differences per design application. Most cases make it a one time flash. Sometimes that "flash" is operation in/with a special gas atmosphere.
A more conventional approach would be to learn more about the various effects of raising and lowering the fillament voltage. There is an entire science to the fillament voltage (way to much for this reply) and it's effects on the operation/emission of the tube. I'm relating this to the smaller tubes which are not normally rebuilt. I've purchased rare/expensive tubes and varied the fillament based on the remaining emission. The tube is still in continous service at it's normal operating parameters. I just keep a closer eye and tighter controls on it.

Best Luck

>grid at 100V is no different than 150mA into the plate of a receiving
>tube at 100V anode potential. Its still 15W either way.

Not necessarily. The heat energy (joules) imparted to a resistance is
I^2*R*t. The heat energy (joules) due to kinetic strikes is M*V^2*t.
They are not necessarily equivalent. The mass of an electron is 9.1e-31
kilograms. There are 6.24e18 electrons per ampere, or 9.36e17 electrons
per second in a .15 A current flow. That gives a total mass of 8.5e-13
kilograms per second for the current flow. The question is then, what's
the electron velocity in the vicinity of the grid?

If it is less than 5.5e6 m/s, the kinetic energy will be less than the
I^2*R value. But the electron velocity in the vicinity of the grid should
be about 1.3e4 m/s since the potential has had such a short distance to act
in accelerating the electron, about 0.0025 meter. That makes the kinetic
energy contribution over 10,000 times less than the I^2*R value.

Either that or I've analyzed the acceleration rate backwards, and the
kinetic impact energy is 10,000 times the I^2*R loss. In either case,
however, they aren't equivalent.

Note, I said earlier that the energy at the grid is 100 eV, but that's
wrong. An eV is the energy an electron gains falling a distance of 1m
through a potential of 1 volt. The distance is much shorter here, so
the kinetic energy gain is less as well. Or is it more? It's late and
I'm not sure.

Hi,

Thanks for reading this. I'm looking for Schematic entry, Board layout, and/or Autorouting Software for the PC. I have access to the real tools (Cadence, OrCAD,...) here at work but I want something affordable for personal use at home. SPICE based simulations would be a plus but are not required. Actually I would not mind several different packages if they all worked reasonably well individually and I could easily trasfer files between them. Bottom line, I'd like to hear what folks out there are using that is reasonably priced (I'm not going to spend $14K for OrCAD at home no matter how much I like it or feel the price is reasonable). So, keep the dicussion focussed to "low price" software please.

Thanks,

Hi Bob,

Don't know what type of tube you are talking about. Small receiving tubes
are initially gettered, big TX tubes are heated and pumped down.

3-500Z's are pumped for several hours, and they also have the gettering
material coated on the anode. So the anode must run red or near red to
activate the getter.

External anode tubes usually have the getter on the end of the filament or
cathode, so they will getter with no HV.

From: Duncan Clark <Duncan@dnamp.com>
Message-ID: <3+k1jAAGoIjyEwsf@dnamp.com>
Source record: 100716

Hi Folks,

There are a number of different 3-500's on the market from genuine Eimac to 'pretenders'. These 'pretenders' are less expensive so what is the catch? Worse perfomance, prone to failure, won't work on 6m or can they used without problems. I am asking on the basis that in the UK we can only run 400W PEP output so they don't get run to the hilt. A single 3-500 run conservatively is more than enough for our licence regs. Given that we tend to pay in pounds what the US pays in dollars ie 1:1 exchange rate (not 1.6:1!), can we safely use non-Eimac 3-500's.

Duncan
G4ELJ

The problem with being on the cutting edge is that you occasionally get sliced from time to time....

Try *WinDraft* and *WinBoard* from "Ivex". http://www.ivex.com They are
shareware, downloadable, reasonably priced, and quite good. $30 each
for 220 pin version. Low cost upgrades for additional pins which you
can purchase by phone.

Mike's Curtis's 9600 Baud Packet Handbook is a good place to start.
Get it from ftp://ftp.tapr.org/tapr/general/9600baud/96man2x0.txt

In general, crystaled radios and synthesized all-mode radios work the
best. Most of the other synthesized FM radios work, but not very well.
They may say "data ready", but they're not.

Many of us are using either TEKK radios or surplus commercial radios,
eg. Motorola Micor or Mitrek. Mod instructions for these are available.

Tom, W8JI gave my callsign wrongly as S59A and I am the person who thought that instantenous plate voltage can never exceed 2 x DC value as my internal model was strictly linear which is NOT the case with overdriven but lightly loaded tube (or transistor). I Measure-d my SB-220 and found RF voltages exceeding DC with antenna shortened. I almost melted output coax connector but it was worth the effort as a new insight into the actual physics was gained.
Following the claims on some fancy phenomenons from California, I got a feeling that a gentleman lives close to Hollywood. Fuse resistors call for outright disaster with their "speedy" action. At least, don't use flamable ones...

Blue glow would appear to be a normal trait of this family of tubes. A buddy of mine, KD6QFZ, built a dynamic tube tester for this family of tubes and noted that after testing dozens of 4CX250, 4X150, 4CX350s and their 24 volt fil equivs. that all had a purple glow visable through the ceramic material. The glow varied in intensity with plate current flow and was quite bright at full rated plate current. No other abnormal conditions were noted and the tubes performed to specification in RF applications both HF and VHF. I sure would not toss the tubes based on a little inonized gas!

>
> Hope someone has an answer to this,
>

There are two reasons for a blue glow on a ceramic envelope. The first
reason is ionizing air--i.e., a gassy tube. The second reason is electrons
striking the inside of the envelope. If a blue glow can be seen during
receive, the tube is gassy. If the blue glow occurs only during transmit,
not to worry. The vacuum is good.

When using low screen voltage tetrodes like te 4CX250..., it is important
to use the shunt-type screen V regulator because of the imminent danger of
reverse screen current. A sample circuit can and discussion thereof can be
found at my Website:
the URL is
http://www.vcnet.com/measures/

NOTE: tubes made with manganese-bearing ceramic envelopes (Svetlana and
RCA) are much less likely to glow. Manganese-bearing ceramic can be
identified by a purple colour---as opposed to the white color of pure
aluminum-oxide ceramic material used by other manufacturers.
Manganese-ceramic improves the flowability of the silver-solder that is
used to bond the ceramic envelope to the metal seals.

> Any insight or preferably experience would be apprieciated.
>

I know some hams who were successful in using 4kV in the Drake L4-B. The factory-stock bandswitch, tuning capacitor, and blocking capacitor can withstand the increased voltage. With a triode, increasing the anode supply voltage means increased gain. This means that the 3-500Zs can be driven to full output with around 100w instead of the typical 125w. There is, however, a trade-off to more gain.

Even though intermittent vhf parasitic oscillation is rare in the L4-B, with a substantive increase in supply voltage--and gain--, more instances of such oscillation have been reported. This problem can be lessened by using lower vhf-Q parasitic suppressors. With lower vhf-Q suppressors, the vhf load R on the anodes decreases. Less vhf load R means less vhf gain, and improved vhf stability. (see "Parasitics Revistited" in the Sept. and Oct. 1990 issues of QST.)

Another problem is that the factory-stock relay in the L4-B is not quick enough to keep up with modern radios. Thus, high speed t-r switching is needed to avoid hot switching. See the Jan. 1994 issue of QST magazine, "The Nearly Perfect Amplifier". Additional info on high speed switching can be found at my Website. Info on the somewhat-surprising pep capabilities of Peter Dahl's Hipersilï¿½ transformers is also available. See *Amplifiers*..... the URL is
http://www.vcnet.com/measures/

A multitap secondary HV transformer is the most efficient and cost effective means of reducing the anode supply voltage. Peter Dahl charges little for each additional secondary tap. For CW, RTTY, and FM, a 60% secondary tap is about right.

I would like to put together small and inexpensive iambic paddles for the car. I use a Brass Racer at the house but I wanted to see what I could put together myself for mobile use. I'm experimenting with double-sided copper PC board from Radio Shack, but it is very thick and doesn't have much "flex" to it, so I'm afraid if I proceed with that plan my hand will become fatigued if I use it long.

I'd like to find some material I could use for switches that wouldn't take too much force to actuate and could last many thousands of closures and openings.

Has anyone invented this wheel already?

One option is to use a small inverter; my partner & I run an old CDR
rotator on a 150Watt inverter along with 3 flourescent lights in a van
set up for VHF+ contesting; the added convienence of the inverter is
great. They are available at Walmart for $60-$80.

I have just finished a product review for WinBoard and WinDraft
by IVEX (these programs are also offered by NTE!)

I liked both programs!

If you use OrCAD, you will be happy to note that the OrCad
libraries may be imported into these programs. The programs
are available as demo "shareware," with a 100-pin limitation.
Otherwise, you pay-for-what you need; and can upgrade by
purchasing a new serial number.

My product review of the IVEX programs will appear in the upcomming
Winter issue of Communications Quarterly Magazine, and also were
mentioned in my Radio Connection column in the Oct. Popular
Communications Magazine.

Hi Duncan,
In article <3+k1jAAGoIjyEwsf@dnamp.com>, Duncan Clark <Duncan@dnamp.com>
writes:

>There are a number of different 3-500's on the market from genuine Eimac
>to 'pretenders'. These 'pretenders' are less expensive so what is the
>catch?

If you ran low HV and dissipation, I think you could get away with the
Chinese 3-500Z's. If not, be careful.

You can have problems with any brand, even Eimac went through periods of
internal gas and weld problems, but all in all the tubes made by Amprex
and Varian are many times better than Chinese 3-500Zs.

The Chinese tubes have poor fitting components (like anode connectors),
gas troubles, and weak envelopes. Emission drops rapidly, and the anodes
won't stand 500 watts of dissipation for long. Even if the anode does, the
glass fails. I still look at samples on occasion, and they are improving..
but they still have a distance to go.

Due to other obligations and the worst case of the flu virus in 23 years, updates to our Ham Radio Online web site have been a little slower than normal this month. But we are still busy adding new stories:
- just added an overview of GPS and GLONASS navigation technologies
- We've republished an excellent article from Richard Perez of Home Power Magazine detailing what happened with lightening blew out radio telephone service and started a forest fire - and the surprising role that ham radio operators played in controlling the fire.
- For history buffs, we're running a story on the importance of Morse Code back in 1871 during the Great Chicago Fire.

And as usual, we have real-time propagation and aurora condition reports, disaster situation reports, equipment info, links to other sites, and so much more.

Ham Radio Online is a self funded, classy online "magazine" devoted to ham radio. Stop on by and enjoy at http://www.hamradio-online.com

We should be back to our regular update schedule very soon.

Tom, Rich didn't ask "who else has seen the effect", he said
(paraphrased) "it's funny that ***EIMAC*** didn't write about it in
their material".

Please address *his* comment.

My apology here, Tom. I don't have time for word games either. I
misinterpreted your statement to mean that the tube's rated grid
dissipation was not 4 watts, when what you were actually saying was that
"at this point" (paraphrased, and referring to some particular point on
the graph) the dissipation was not 4 watts. My fault. I misinterpreted
your statement.

OK, Tom. Let's start with something VERY fundamental:

For the umpteenth time: WHO IS "XXX" AT EIMAC THAT WROTE THE EMAIL YOU
QUOTED???

That's a pretty simple question, but you keep ignoring and evading it.

If we are going to discuss this rationally, then let's dispense with the
cloak and dagger secrecy, OK?

Rich is not hiding anyone's identity. I can't believe that you have no
idea who sent you that email from Eimac. So, please tell us who wrote
it. Why not?

That oughta be pretty simple from what I can see from here......

73, Tom KJ5IE

2964. Please Help - looking for 150MHz FM transmitter schematic

Newsgroup: rec.radio.amateur.homebrew

From: erazmus@wantree.com.au
Message-ID: <56juq9$vkr@news.wantree.com.au>
Source record: 100650

Hi,

I'm looking for a schematic for a 150MHz FM transmitter for 100mW output, running off a battery DC supply from 5V to 12v and want to modulate the transmitter by a bitstream generated by a PC or micro.

Anybody know where I can find a schematic for this ??

Given the recent overload in news-groups could some-one email me ?

Rgds

Yeah, I've gotten a couple of responses to this so I tweeked it a bit but still not sure if it's any better, I think I need to make my main banner smaller as it seems a bit large I will work on this hopefully this weekend and see if it gets better. I'ma bit spoiled as I have a fast dedicated connection so I move stuff through rather quickly. Sorry for the inconvenience folks :)

> >>I measured 3.7 kV peak. The supply voltage was ~ 3kV when mistuned.

.......Tom said:
"The RF voltage in a tank can soar to several times the HV supply when the tank is underloaded."

My dictionary says:
SEVERAL: Being of a number more than two or three but not many.
Thus, several times 3kV is more than 9kV. 3.7kV is what was measured.
What is the point in citing a test that disproves your statement, Tom?
Furthermore, the cases of destructive arcing I am familiar with did not occur during tuneup.

> >Under above conditions, SB-220 tuning capacitor tested for 3.5kV may arc!

My SB-220's tuning capacitor does not arc during mistuning with 100w drive. However, with Heath's factory-stock high vhf Q parasitic suppressors, the tuning capacitor infrequently arcs, but not during mistuning, during normal operation. With lower vhf Q suppressors, this is not the case. Why do we need higher vhf Q if we are trying to build a vhf dampening device, Tom?

Tom has argued that virtually all of the vhf current passes through the suppressor resistor, and that virtually none of the vhf current passes through the suppressor inductor. Is this the case? In a typical 8877 vhf parasitic oscillation suppressor, the resistance is around 50 ohms and the inductance is roughly 45nH. A typical anode resonant frequency for an 8877 amplifier is about 100MHz. The reactance of a 45nH inductance at 100MHz is 30 ohms. If a 50 ohm resistance is connected in parallel with a 30 ohm inductance, which component will carry the most current, Tom?

Tom: What is the identity of Eimac's Mr. XXX? Why does Mr. XXX list a bogus e-mail address?

---

e-mail copy to Mr. Rauch

Source record: 100655

Peter Dingemans <129432pd@mstore.eur.nl> wrote:

Peter,
For what it's worth, I found that 4CX250B tubes would become gassy in about 6 to 8 months of operating in a broadcast enviroment. Since these are surplus tubes that may be the problem if they were used. I used a bunh of Surplus tubes but they were new in the sealed can when I put them in the transmitter. As to the Blue Glow, I never looked at a 4CX250 when operating as they were in the RF Cavity. But based on experiance with Glass tubes I would suspect a Blue glow as a gassy tube.

Mario, without a doubt, your test method is without peer! I would
never have thought to short an antenna that was connected to a "over
driven", un-loaded SB-220 to compare the DC with the un-loaded RF
voltage. By the way, what was the exact magnitude of the RF voltage
and the instrument used to measure it? Or, was "almost" melting the
output connector the guage you used to determine the RF voltage was
twice the DC voltage?
Jesse, W6KKT (50 miles north of Hollywood)

2974. Re: Does RF Parts have web site?

Newsgroup: rec.radio.amateur.homebrew

Allan Dobler <doblera@cadvision.com> shared these priceless pearls of wisdom:

->Hi, does RF Parts in San Marcos, Ca. have a web site?

I don't know; I searched for an hour the other day and came up dry. I saw the owner's picture on the cover of a magazine last week, and it brought to mind the last time he and I worked together was on the board of directors of the San Diego VHF Club back in the early '60s. If you find a site, tell Merit to drop me a line.

Do you have a FAX number? I'll fax you a schematic. No scanner on this end for JPG or GIF.

But you can get the Ramsey kit for about $35. It's a 10X Amp with a max out of about 35 Watts. so 1 in may get
you 10 out, 3 to 5 in gets you 30 to 35 out.

I have one and aside for the TX/RX switching the project took me about 25 minutes.

w6kkt@frazmtn.com (W6KKT Jesse) shared these priceless pearls of wisdom:
->Hi Tom, what timeing would you recommend for the close / open and how
->would the average ham go about achieving it?
->73, Jesse, W6KKT

You say you don't want to use a DPDT relay at the input/output. Is this for cost or ease of design? If the cost of the relay isn't a big deal, use a DPDT relay with one set of contacts passing DC to the relay you want to close second. Then even if the DPDT relay fails, you won't blow up the whole amplifier because the second relay will never come on. Of course, one SET of the contacts on the DPDT could fail and cause catastrophe, but I'd gamble this way instead of some sort of timing circuit.

Source record: 100664

Hello, I posted this once before and got a few replies but they weren't good enough. I hope someone can help me out.

I have a repeater that we want to put a ten meter link on it it all works fine except for when we come out of transmit on the ten meter transmitter, when it goes back to recive (it is a tranciever) a strong spike comes out of the audio line. I need to supress it. for it blows out audio mixer chips. I tried the back to back diode thing. that did help and may keep the chip from blowing now but the pulse is still quite strong. Does anyone have an idea to lower this more?
Thanks.
Joe WB9SBD

2979. FAX SSTV RTTY WEFAX with SoundBlaster: OK!

Hello.
I've just updated my FTV program, which does FAX & SSTV using a SoundCard, to decode Baudot using the same (FM) demodulation engine.

Here is a run down of the more interesting features:

(1) It keeps the demodulated signal in memory, so that the signal can be analysed again at a different keying rate or polarity! Garbage can be resampled on the fly, which means that minutes of received signals decoded at the wrong baud rate or keying polarity are recovered, on the fly, while still receiving.

(2) Keying rate and polarity are analysed automatically - standard baud rates are automatically set following analysis.

(3) Tuning oscilloscope available at all times, without loss of copy.

(4) Program works in real time.

(5) I wrote it, and I love it - I myself can't believe it works so well!

Download your copy of FTV from my web site, at:
http://www.geocities.com/SiliconValley/2504

System requirements, and the standard features of FTV are described in the following page:
http://www.geocities.com/SiliconValley/2504/ftv.htm

By the way, AM signals from low orbiting weather satellites are also decoded - no extra interfaces needed. Demodulation mode is user selectable in software.

Hope you all have a load of fun receiving 'words and pictures' - I hope to get some feedback !

All the best from Brian, 9H1JS, on the Island of Malta.

> P.S. I don't want to get involved in O.J. type proofs from certain letter!

Hi Mario-

I understand what you measured, and I don't dispute your findings at all. However, while Tom has been talking about "shorted loads" and that sort of thing, Rich has been discussing arcs and other misbehavior that have happened in amps where the antenna was NOT shorted, damaged or compromised in any way. And, while the high anode voltage mentioned in this thread was indeed there, it was with one or more of the tuning capacitors WAY out of tune, and actually adjusted for max anode voltage.

Once again, this does not dispute Rich's claim.

Rich was talking about an amp arcing and otherwise having problems in a properly configured system, and while in normal operation.

Measuring the anode voltage under abnormal conditions does not in any way prove that the same anode voltage exists under normal conditions.

Am I missing something here?

73, Tom KJ5IE

PS: I say, keep the electronic grid protection and add the carbon "fuse resistors" if the amp is unstable. You just can't have too much grid protection, or tube protection in general. But, Rich's claim that the electronic protection may be insufficiently robust for a cataclysmic failure sounds correct to me.

From: daveb@buffnet.net
Message-ID: <56j0up$940@buffnet2.buffnet.net>
Source record: 100669

Hi All,

Ok here is the deal. I'm looking to increase my output on 2 M by 3dB.
I'm planning to mount another MRF-151G on my current heat sink.
What is the cleanest way to split/combine the inputs & outputs.
The design is based on the Motorola app. note.
The simplest I can think of would be 1/4 wave sections of 59U.
I've seen four port devices that when one port is terminated in 100
ohms one port is an imput and the other two are in quadrature.
Something like a wilk combiner.

Any ideas ??

Thanks

daveb@buffnet.net

Source record: 100671

This is a good question. I wrote a letter to ARRL with an answer from the Lab Supervisor Ed Hare. His answers were that we've always done it that way and we don't want to get anybody to go ballistic with changes. I hope you write a letter to him as well. My letter showed where their own publications as well as the commercial world do it different than they do. Even an article about measuring Intermod in QEX didn;t use their method. You certainly have hit on a sore spot. Thanks Jim Ford, N6JF jimford@netcom.com

> lost. Any help would be greatly appreciated. Thanks.
> Tyler
> N3SPD

Starting with the answer -- pre-emphasis and de-emphasis is used because it increases the signal to noise ratio of the the received signal.

Basically the logic goes like this: the noise Power Spectral Density (PSD) in an FM system is proportional to the square of the frequency and the PSD of signal is directly proportional to the frequency. So if one were low pass filter the output of the FM receiver (de-emphasize) one would eliminate more noise power than signal power which is a good thing... Having done that, the transmitter is high pass filtered (pre-emphasized) to make the audio response flat.

73's,
Bob

Greetings!

E-LAB Digital Engineering, Inc. is pleased to make freely available our new
Electronics Internet Resource Directory!

This directory is a collection of many internet sites of use to
electronics builders, designers, and engineers. It is divided into
40 categories, with each category containing many hot-links to companies
and/ or web pages containing information on topics from Compilers to
Code Examples to Components Distributors.

The directory is available at http://www.netins.net/showcase/elab
You WILL want to set a bookmark!

We also invite you to check out our products, such as our new line of
integrated circuits for embedded design.

Thanks,

Todd Peterson

2991. Commercial VHF low radios. Which ones have easily scavenged PAs for 6 FM ?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-17 00:00:00 UTC
From: PCG@zipnet.net
Message-ID: <56nd5c$68n@news.ziplink.net>
Source record: 100589

Greetings fellow home brew mavens.

In an effort to populate a new VHF band in the New England area, members of our local 2 M repeater society are going to assemble some Ten Tec 6M FM kits as a group project. We have about ten people who are interested.

Since the kits possess finals that put out about 5 W, we need to find a 6M FM amp kit to accompany these radios. A fellow ham suggested that many solid state commercial boat anchors have PAs that can easily be removed and adapted for use with these Ten Tec units. He seemed to think that Micors, and certain other GE units might provide the needed parts, already assembled into an easy to remove module.

Can anyone provide concrete details on exactly what radios could be scavenged in this fashion? We would like to find something that will generate 100 watts of output power.

Thanks
Chris

3.7kV is what was measured. Neither 6kV nor 9kV was measured. In my
opinion, most people would take 'a couple of times' as around 6kV, and take
'several times' as around 9kV.

This voltage does not 'build' in my SB-220, or in my other amplifiers
either Interest on a savings account builds.
Why mention the anode voltage when we are talking about the peak voltage
on the tune capacitor?
None of this discussion about deliberate mistuning really matters, Tom.
In the SB-220, tune capacitor arcing occasionally occurs during normal
operation, not during experiments where the tune and load controls are
mistuned for maximum voltage across the tune capacitor.
My SB-220 tune capacitor used to arc occasionally until I lowered the
VHF-Q of the VHF parasitic oscillation suppressors. After lowering the Q
of the VHF parasitic suppressor, the pecuilar tune-capacitor double-peak in
40m tuneup disappeared. Other folks have experienced similar results. In
the Drake L4-B, the tune-capacitor double-peak in 15m tuneup disappears
when lower Q suppressors are installed.

> was the resistor, not the inductor. I've said repeatedly the primary path
> for VHF and UHF signals is through the resistor, and the primary path for
> HF signals is through the coil ### IN A PROPERLY DESIGNED SUPPRESSOR ####

When you telephoned me in 1990, you talked about properly designed parasitic suppressors. However, you offered no information about such animals. You brought up the subject of proper suppressor design again here, and yet you still provide no information.

If an 8877's VHF parasitic oscillation suppressor resistor is 50 ohms and the (paralleled) suppressor inductor is 30 ohms, the lion's share of the VHF current would seemingly pass through the 30 ohm inductor and the lesser, remainder of the total current would seem to pass through the resistor. However, perhaps I am in error.

Tom: Are you suggesting that the primary path of VHF current is through the paralleled 50 ohm resistor? If you maintain that most of the VHF current passes through the 50 ohm resistor, Tom, please show us the mathematical solution that led you to your conclusion.

Does anyone have any schematics for the old Palomar tube amplifiers that CBers were using in the 70's? They were the gray box, with about 100+ watts out for 5 watts in.

I would love to get some schematics/diagrams on them, or any amp in the 100-500 watt class that takes about 5-10 watts to drive.

Another ham and I are looking to build from scratch an amplifier for 6 meter use. We were looking over the ARRL diagrams, and got on the subject of those amplifers. I recall a ham in the town where I lived got one of those amplifiers from a CBer that was getting out of the hobby in 1976, and was able to modify the input output tuning for 6 meters, and it worked great.

I would be glad to trade an official NBC 96 Atlanta Olympics poster for a set of prints. I only have 5 left. These are the 3'x2' posters they were selling for $19.95.

Hello congratulation with your licence . I got mine 1.5 years ago and
for some monts ago I wanted to do the same. I have some scematics in
norvegian!!!! And I can scan them in and mail them if you want to.

I also have the htx 202 2 meter .
I have blowed my final transitor twise. The second time it was when
tuning up a my homemade PA using low power... So be careful... looks
like Radioshack "forgot" to make SWR protection
to sell more transistors. I would suggest you used a other radio
tuning up your PA. I saw some posting abuot expensive parts...
Go to a junk party or whatever you call it. And get some old commersial
overstock. Or try to get the parts needed from a local home-brewing
freak.

Or by a used PA as I did. Got it for 30 usd and it cost about 400 usd
new. It gives 85 w a nice power...

Im sure you know someone with the house filled with ham-gear.
Ask if they have anything they dont need.

Ham meetings are great ...easy to get low price gear

Hope this helped, best 73 de LA7EJA

>to start into oscillation intermittently from switching transcients?
>73, Jesse, W6KKT

Let me explain that in a very clear statement Jesse, then there will be no misunderstanding.

If a PA is unstable, and is properly tested or analyzed, any instability or potential instability will show up. If you read back here, and in published text, virtually all of Measure's claims are based on the concept that a tube change, a photon strike, a keying transcient, or some other trigger mechanism sends an PA that behaves well into a sudden oscillation.

We know a few things, or at least can prove a few things. We can inject the anode circuit with a known VHF voltage and measure voltage distribution along the component chain. I did that, and always do that (with a sweep oscillator), in many PA's. I've yet to see a halfway decent layout have a voltage INCREASE, or even a constant voltage, along the tank.

We can measure the tank capacitor, and determine the reactance over a very wide frequency range We can measure the switch contacts and determine the RF voltage available to cause an arc at various frequencies.

We can accurately determine the VHF and HF impedances, feedthrough power, and loss, and from that estimate stability of the PA.

So we can accurately measure many many things that determine stability and what the results of instability will be.

Part of normal testing is raising and lower high voltage, varying bias, and changing input and output loads as operating parameters are changed.

If an amplifier was unsatble, or at the edge of stability, it would show up very clearly in many of these normal tests. It would show up in normal daily operation.

From all of this, it is very safe to say a stable PA doesn't suddenly break into an uncontrolled VHF oscillation when "bumped" by things that go on day after day in normal operation. PA's are either stable, or they are not.

Let me give you an example of an unstable PA, the Dentron Clipperton L. Virtually all Clipperton L's oscillate when the bandswitch is on 15 and ten meters if the loading control is too far closed. The oscillation is in lower VHF to upper HF, and will destroy the suppressor resistors from high energy levels in the tank. But the oscillation is repeatable, and easy to define. The circuit faults contributing to the instability can easily be determined, and nothing about the instability is magic.

When a PA is unstable, it can be made to repeat that instability over and over. The causes of that instability can be determined, and components effected by that instability can be determined by measurement.

It is virtually impossible for a stable PA to go along operating for days, weeks, and years, and suddenly break into an uncontrolled oscillation. The only exception I can think of is component failure as a trigger (ie a ground lead "falls off" a critical location in the PA).

None of this "parasitic stuff" makes sense at all Jessie.

Hi Ian,

As Jesse will confirm, I explained virtually the same thing to him in
private conversation.

When I test a PA for IMD, I use either a variety of tone spacings and
levels, and a variable level two tone test (I call it a three tone test,
although the extra "tone" modulates the two higher tones at less than a
few Hz). I select the worse case result as the spec, and give both the
standard rating and worse case. I always use the industry standard of -dB
below one two of two equal tones.

The reason for using this more complicated method is simple. IMD is often
produced by poor voltage regulation as the power is varied. A standard two
tone test will not show this flaw.

You have your high-pass and low-pass filters backward - if you can call
them that. The receiver deemphsizes the high frequencies. That is,
high
frequencies are attenuated; this more closely resembles a low pass
filter.
Conversely, the transmitter emphasizes the high frequencies as in a high
pass filter.

Hi,

I am looking for the keying circuit for the delta 1A or 2SRA.

These radios use a single "stereo" 1/8 th inch jack.

I would like to connect a non-Icom speaker-mic to the radio but I don't know the PTT connection or pinout.

If you could help me please e-mail.

Thanks,

Scott Sidener N0WFL

Re: GE Amp modules... Beware of overdirve damage from the TenTec ans
most of the PA strips require about 250 mw of drive. You could use an
attenuator.... Also there are 50 stripline points between many stages.
Some have a jumper strap in-line. Just cut (or remove jumper) strip and
feed where the TenTec drive is appropriate. Woody

I'd recomend you consider a quadrature combiner. I t requires a 90
degree hybrid in the input and the output, arranged so that the phases
all add up correctly. The coupler is most easily made from Sage
Wireline which you can get from Sage Laboratories (508) 653-5671.

I have used the line at the 150 W level at 300 MHz and it works fine.
You can cut your own or for a few bucks they will supply you with the
line pretrimmed and stripped. Basically, its two wires inside a shield
with the impedances arranged so that a quarter wavelengthmakes a 30
dB, 90 degree coupler. Thier catalog has an eplanation of how it
works. The advantage of this kind of coupler is that mismatched power
from unbalance between the two amplifiers ends up in the waste load.

It's a 4-port device and can be used as a splitter with two equal
outputs and an isolated output that just sees mismatched reflected
power from the two loads and a combiner with two inputs, a sum output
and a difference output.

Hi and thanks for reading this. I hope you can help me figure this out.

I want to key the rig from the parallel port of the computer with a logging program like CT. The rig is a Kenwood TS-830S which uses negative keying. I built a K3KU type parallel interface which should key both
positive and negative keyed rigs. When I attach everything, it imediately keys the rig.

I don't know enough about transistors to figure this out on my own in real life. If you are familiar with the CT manual. It calls for a PNP and a NPN transistor. I am using a 2N5401 and a 2N5551.

Thanks in advance
Raj VE6RAJ

>
>How do you match impedances from a cordless phone whip antenna to a 50 ohm
>line? Any help would be greatly appreciated. Thanks.
>73 de N3SPD Tyler

I usually have the most problem getting the stupid plastic cases open.

The articles that I have seen suggest that you remove the whip from the base,
and replace it with a chassis mounted bnc connector. You don't have to
worry about impedance matching since power output is so low. Let us
know how well the external antenna works (how much it improves reception).

The noise in FM channels is frequency dependent. Pre-emphasis boosts
the audio in the the frequency range where the noise is greatest, but
the audio tends to be weak, and de-emphasis corrects this in the
receiver. It is also done for tape recordings and vinyl disks.

If I remember correctly, it is the high frequencies that are boosted.

Actually, I believe, pre-emphasis produces a similar (if not identical)
effect to using phase, rather than frequency, modulation.

3013. Re: Good source for amplifier tips

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-17 00:00:00 UTC
From: w8jitom@aol.com
Message-ID: <19961117011000.UAA24623@ladder01.news.aol.com>
Source record: 100675

Hi Rich,

I can see this is like pulling teeth with a tweezer. Let's cover one area at a time.
In article <measures-ya023180001611960220390001@news.vcnet.com>, measures@mail.vcnet.com (R. L. Measures) writes:

>.......Tom said:
> "The RF voltage in a tank can soar to several times the HV supply when the
>tank is underloaded."
>
>My dictionary says:
>SEVERAL: Being of a number more than two or three but not many.
>Thus, several times 3kV is more than 9kV.

Two times 3 KV is six, not nine. Several times is any amount more than two or three times.

>3.7kV is what was measured.

RE the SB-220, here is what I said:
In article <5549of$269@newsbf02.news.aol.com>, w8jitom@aol.com (W8JI Tom) writes:

>Eventually, if equilbrium isn't acheived first in dissipative losses,
>something gives.
>The SB-220, when improperly loaded, can produce over 4 kV peak on the
>input end of the tank. The tube peak anode voltage is over 7 kV. Until
>something "gives" or the energy falls back in equilbrium, the voltage
>builds. Unfortunately it is often the tuning capacitor or bandswitch that
>arcs.
>
>This effect can be measured and documented, it is not a matter guessing
<<End of my statement>>.

Mario measured ~3.7 kV, within 500 volts of what I measured for Heath during tests of SB-220's and SB-221's. Now let's compare that to your claims.

In a message dated 96-11-07 12:03:17 EST, Measures wrote:

> However, I do know that in a 3-500Z g-g amplifier that uses a 3000V anode
>supply, the negative-going change in anode voltage during the conduction
>cycle of the 3-500Z is about 2700vp (volts peak), which coincides with the

>peak in anode current. At this peak, the anode to (grounded)grid voltage
>is about 300v. {3000v minus 300v = 2700v} When the amplifier is
>underloaded, the tube saturates, and the anode to grid voltage (at the
>anode current peak) is about 150v. In other words, the negative-going
>change in anode voltage is about 2850vp. It's a long way from 2850vp to
>the 5500v or more needed to arc the bandswitch.

So you claim about 2850 volts peak, and I said a SB-220 can produce over 4000 under conditions of improper tuning. Mario verified 3700 volts in a crude single test. The plate tuning cap had a minimum spec voltage of 3.5 kV at Heath, and the bandswitch was speced at the same voltage between the ten meter tap and the rotor. In a steady state test of one PA, Mario verified a voltage exceeding Heat's minimum QC spec breakdown rating of the tuning cap and switch.

My data comes from a series of tests on six PA's, three 220's and three 221's. I measured as high as 4300 volts peak tank voltage when some PA's were mistuned.

>Tom has argued that virtually all of the vhf current passes through the
>suppressor resistor, and that virtually none of the vhf current passes
>through the suppressor inductor. Is this the case?

No, I argued that the dominant Q determining component at VHF and higher was the resistor, not the inductor. I've said repeatedly the primary path for VHF and UHF signals is through the resistor, and the primary path for HF signals is through the coil ### IN A PROPERLY DESIGNED SUPPRESSOR #### .

Before we start on that, let's clear up this other stuff. We now seem to just go in circles, and that is a waste of time. If you'd like to discuss parasitic suppressor behavior, continue the SB-220 test discussion, or discuss PA's that can produce up to 10 times the dc supply voltage we can do any of that. Take your pick.

After that we can move on to your other questions, but let's agree on things and get them out of the way so we quit running in a closed loop.

3014. Battery Charger

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-17 00:00:00 UTC
From: georgehe@unix.asb.com
Message-ID: <E0zrpq.56n@news2.new-york.net>
Source record: 100676

Thanks for reading this. I use a car battery for standby/emergency use with my gear. I am painfully aware that regular lead acid batteries are a poor choice for this purpose, but they are plentiful and cheap.

I'm looking for a "battery maintainer" circuit. The circuit would trickle charge the battery up to the ideal voltage, then shut down and light a charged led. If the battery voltage drops a volt or so the trickle charger kicks in to keep it up.

This device is sold commercially as a "battery maintainer" for RV or Marine batteries in the off season. Costs about 40$ too !

I would like to built one of these things in a nicer case with a few customizations. (minor stuff- switch and meter)

Any help would be appreciated. Any pearls of wisdom (other than the obvious) would also be appreciated too !

I'm into ARES/RACES and this sort of stuff is nice for the niche, so to speak.

>Jesse, W6KKT (50 miles north of Hollywood)

Hi Jesse,

One manufacturer requires a short load test on ever PA leaving the factory, as well as an open load at full drive, to weed out close wires and weak components in tanks.

The goal is to make sure the plate tuning cap or an intentional gap arcs before the switch, and any weak components (like padding capacitors) fail.

One process of designing a new **Amateur** PA is to run 15% more than rated HV, short the load, and apply full drive. Components are sized to just barely be beyond arcing under that condition. Commercial units enjoy more protection and margin.

>whole amplifier because the second relay will never come on. Of course,
>one SET of the contacts on the DPDT could fail and cause catastrophe, but
>I'd gamble this way instead of some sort of timing circuit.
>
>Jim

That still requires a delay included for the output relay, and supply
voltage for the input relay must be taken from across the output relays
souces (but without the delay) and routed via an extra set of contacts on
the output relay to the input relay.

The output relay needs to always close first, and open last.

In article <328E1C61.4014@mail.teclink.net>, "Tom C. Brown, Jr." <madison@mail.teclink.net> writes:

>I understand what you measured, and I don't dispute your findings at >all. However, while Tom has been talking about "shorted loads" and that >sort of thing, Rich has been discussing arcs and other misbehavior that >have happened in amps where the antenna was NOT shorted, damaged or >compromised in any way.

How does Rich know the load was good and the amp was tuned correctly Tom? Was he actually at the person's house watching everything, including SWR and exciter peak power, when the failure occured?

For two examples:

1.) Many exciters output short bursts of higher than normal drive power before the ALC kicks in.

2.) Sometimes the loading cap may flash over, this unloads the tank.

3.) The antenna relay may not "hit" right.

>And, while the high anode voltage mentioned in >this thread was indeed there, it was with one or more of the tuning >capacitors WAY out of tune, and actually adjusted for max anode voltage.

No, it can happen with NORMAL tuning if the load moves the correct direction. It can even happen if the exciter spikes the PA **without** any load fault.

>Once again, this does not dispute Rich's claim.

It's a lot like arguing religion or UFO's isn't it. Even if the claim flys in the face of science, there will be people who believe.

>Rich was talking about an amp arcing and otherwise having problems in a >properly configured system, and while in normal operation.

He doesn't know that unless he was there with test equipment hooked up. I doubt he even has the correct equipment, maybe he can give us an idea of what he has for measurement devices.

>Measuring the anode voltage under abnormal conditions does not in any >way prove that the same anode voltage exists under normal conditions.

>Am I missing something here?

Yes.

1.) How an oscillator works.

An oscillator either oscillates or it doesn't. It doesn't suddenly "ring" or "gong" into oscillation. Photons won't suddenly cause a circuit to oscillate, neither will keying transcients.

2.) Grid dissipation

Varian rates their 8877 grids at 25 watts, even though Rich claims almost 500 watts is required to hurt them. He claims the gold melts from I^2 R losses, when the primary heat mechanism is electron bombardment.

3.) Impedances

The impedance of the plate capacitor. It is impossible for the tube to excite the bandswitch or tuning cap with enough VHF energy to make them arc.

4.) Emission limitations

The 3-500Z saturates at about ten amperes of cathode current even if the grid is pulled to thousands of volts positive, yet Rich claims the tube will draw hundreds of amperes in a parasitic.

5.) Gold migration.

Rich claims gold only leaves the grid when it "boils", yet gold migration occurs even if the gold is still a solid.
>
>PS: I say, keep the electronic grid protection and add the carbon "fuse
>resistors" if the amp is unstable. You just can't have too much grid
>protection, or tube protection in general.

Wrong. Carbon resistors on the grid are idiotic for protection. The current required is too large, the time delay too long, and if the resistor opens the grid is free to float high.

Secondary emission in an operating tube can cause this effect, as can leakage.

>But, Rich's claim that the
>electronic protection may be insufficiently robust for a cataclysmic
>failure sounds correct to me.

Me too, but Rich seems to want to throw the baby out with the water. The correct solution is to add an energy absorbing type resistance in the anode, and properly protect the grid overload system.

The primary mode of grid failures, as Varian claims and experience verifies, are load faults or mistuning. Varian even mentions that in service bulletins. Rich confuses anode to grid faults due to gassing.... with parasitics.

3022. Low Frequency Reception Boston Area

Is anyone in the Boston area receiving by 1 watt beacon on 187.55 kHz? The ID is "WA" and runs continuously.

My signal typically gets out about 50 miles from my home base in Andover, MA, with good receiving equipment, and favorable conditions.

Tom, are you absolutely sure it's impossible for a unstable amplifier
to start into oscillation intermittently from switching transcients?

And someone else in turn will disagree with that...

>For example, I could say that the standard

>VOM in the air. But that would give an incorrect reading of the
>static field, so it is the wrong way to make the measurement.

Now that's true - but it has nothing to do with this discussion. Gary's example is merely an inaccurate measurement.

This thread is about two measurement methods that are both defined, and that definition re-stated along with the results: either "X dB below PEP" or "X dB below either of two equal tones". Measurement accuracy is a separate issue that applies equally to both methods.

We could continue to discuss which is the "better" or the "more useful" or the "more appropriate" measurement to make, but neither measurement is "wrong".

Let's change the subject: how good are two-tone methods anyway?

If we are concerned with the ability of one SSB (voice) user to interfere with users on nearby frequencies, measurement of exclusively low-order intermod proucts with static tones is a pretty poor method.

Most amateur reviews (and some professional specifications) concentrate far too much on low-order products. We usually see reports of 3rds and 5ths with a tone separation of about 1kHz, and maybe a plot out to +/- 10kHz, but that's all.

Wideband splatter is caused by much higher-order IPs than the ones we usually measure, and published test results don't usually show whether those IPs drop quickly into the noise or tend to remain at audible levels over a very wide bandwidth. Also, many transmitter / power-supply combinations will give quite different IMD performance when allowed to settle to steady two-tone conditions than when they're being kicked

around by a pulsed two-tone signal or real voice modulation.

You can see a much more realistic picture of spectrum occupancy by setting a modern spectrum analyser to "peak hold" mode, and leaving it to run for several minutes of normal voice modulation. What comes out is an envelope plot of the highest signal levels seen at any time, as a function of frequency.

Because the voice modulation is wideband rather than single-tone, you can't see distinct peaks from the separate orders of IPs. The output looks very much like a noise-sideband plot, a continuous line with a general downward trend at each side of the main signal. There are statistical fluctuations because the analyser may not be looking at a particular frequency when a very short peak occurs, but those errors are reduced if you run the test for a longer time.

The main virtue of this method is that it simulates on-air use under much more realistic conditions than a static two-tone test. I don't think it completely replaces the traditional test method, but it's certainly a valuable addition to it.

Any comments, please - particularly from somebody who has tried it?

Everything from photons to grid dissipation is different in you
amplifiers, it only makes sense that PA voltage behaves differently there
also.

> Why mention the anode voltage when we are talking about the peak voltage
>on the tune capacitor?

Why not? It gives users a feel for the stress on the tube.

> None of this discussion about deliberate mistuning really matters, Tom.

It does. If tuning is correct at a given output but...

1.) The antenna relay fails to transfer and/or the loading cap arcs.
2.) Excessive RF drive is applied.
3.) Something in the antenna or tuner arcs

tank voltage and anode voltage can soar. This can cause the tube or tank
components to arc over.

>In the SB-220, tune capacitor arcing occasionally occurs during normal
>operation, not during experiments where the tune and load controls are
>mistuned for maximum voltage across the tune capacitor.

I would suggest someone tune the PA properly then, or correct the ALC
overshoot in the exciter.

Of course, it lower HF tank Q.

Rich, read back. I described methods used to design suppressors. Unlike
you, I believe each system is different, and requires different solutions.
